

House Mouse Eradication from the South Farallon Islands Draft Environmental Assessment

January 2011

Lead agency:

U.S. Fish and Wildlife Service
San Francisco Bay National Wildlife Refuge Complex

Abstract

The United States Fish and Wildlife Service proposes to protect and restore the ecosystem of the South Farallon Islands, particularly seabirds and other native biological resources, by eradicating non-native house mice and preventing their future reintroduction. In accordance with the National Environmental Policy Act (NEPA) and its associated regulations, the Service has prepared this Environmental Assessment (EA) to determine whether mouse eradication on the South Farallones would have significant impacts on the quality of the human environment. The Service has considered three alternatives to address the problem of non-native mice on the South Farallones:

- A. No Action, which would allow mice to remain on the South Farallone Islands maintaining the status quo;
- B. Mouse eradication with an aerial brodifacoum broadcast as the primary technique; or
- C. Mouse eradication with brodifacoum delivery through the use of bait stations as the primary technique.

The Service is soliciting comments from the interested public on this Draft EA. If no significant impacts to the human environment are identified, and public comments do not warrant major changes in the proposed action, the Service will then issue a Final EA with a Finding of No Significant Impact, and implement the action.

Public Comment Period:

April 4, 2011 through May 16, 2011

Please address comments to:

Gerry McChesney, ~~Acting Refuge~~ Manager, Farallon NWR

Executive Summary

The Farallon Islands, or Farallones, are about 28 miles west of the Golden Gate and the city of San Francisco, California. This group of islands is managed by the U.S. Fish and Wildlife Service as the Farallon National Wildlife Refuge. The Farallones' isolated nature, varied and extensive habitats, and adjacent productive marine environment makes them an ideal breeding and resting location for wildlife, especially seabirds and marine mammals. The Refuge comprises the largest continental U.S. seabird breeding colony south of Alaska, and supports the world's largest breeding colonies of ashly storm-petrel, Brandt's cormorant, and western gull.

The South Farallon Islands, the island cluster within the larger Farallones group that contains the vast majority of the land area, have sustained ecological damage over many years from the presence of non-native house mice. Mice eat invertebrates, seeds and other plant matter, and possibly the eggs of nesting seabirds (mice have even been found to prey on seabird chicks in the nest on other islands). On the South Farallones, mice also artificially sustain burrowing owls that arrive from the mainland and prey heavily on small seabirds.

The purpose of the proposed action is to meet the Service's management goal of protecting and restoring the ecosystem of the Farallones, particularly seabirds and other native biological resources, by eradicating non-native house mice. Eradicating house mice would likely prevent burrowing owls from staying on the islands to prey on seabirds. Mouse eradication would also likely benefit native amphibians, invertebrates, and plants.

In accordance with the National Environmental Policy Act (NEPA) and its associated regulations, the Service has prepared this Environmental Assessment (EA) to determine whether mouse eradication on the South Farallones would have significant impacts on the quality of the human environment. Using the guidelines set by NEPA, the Service has considered three alternatives for addressing the problem of non-native mice on the South Farallones:

- A. No Action, which would allow mice to remain on the South Farallone Islands maintaining the status quo;
- B. Mouse eradication with an aerial brodifacoum broadcast as the primary technique; or
- C. Mouse eradication with brodifacoum delivery through the use of bait stations as the primary technique.

Within this EA, the parameters of each of these alternatives are described and their potential impacts to the environment are considered. The environmental issues discussed include:

- Impacts to physical resources including water resources, geology and soils, and wilderness character;
- Impacts to biological resources including impacts from toxicant use and impacts from disturbance;
- Impacts to the social and economic environment, including Refuge visitors, fishing resources, and historical and cultural resources.

The Service is soliciting comments from the interested public on this Draft EA. If no significant impacts to the human environment are identified, and public comments do not warrant major

Executive Summary

- 1 changes in the proposed action, the Service will then issue a Final EA and a Finding of No
- 2 Significant Impact, and implement the action.

1 **1. Purpose and Need**

2
3 **1.1. Introduction**

4
5 The United States Fish and Wildlife Service (“USFWS” or “the Service”) proposes to undertake
6 the following actions on the South Farallon Islands, part of the Farallon National Wildlife
7 Refuge (“FNWR” or “the Refuge”):

- 8 1. Eradication of the non-native house mouse (*Mus musculus*); and
9 2. Prevention and emergency response plan for dealing with re-introduction of mice, other
10 non-native rodents, and other animals to the islands.

11
12 In accordance with the National Environmental Policy Act of 1969 (NEPA) (42 USC 4321 *et*
13 *seq.*, as amended), and Council on Environmental Quality (CEQ) regulations for implementing
14 NEPA (40 CFR 1500 *et seq.*), Federal agencies must consider the environmental impacts of
15 actions – projects, programs, policies, or plans that are implemented, funded, permitted, or
16 controlled by a federal agency or agencies – they propose to undertake. Specifically, Federal
17 agencies must consider the environmental impacts of a reasonable range of alternatives for
18 implementing an action, and make the public aware of the environmental impacts of each of the
19 alternatives presented. If adverse environmental impacts are identified, NEPA requires an agency
20 to show evidence of its efforts to reduce these adverse impacts through mitigation. An
21 environmental analysis, such as this Environmental Assessment (EA), documents that an agency
22 has considered and addressed these impacts.

23
24 This EA will be used by the Service to solicit public involvement and to determine whether the
25 implementation of either of the action alternatives presented within would have a significant
26 impact on the quality of the human environment.

27
28
29 **1.2. Purpose of the Proposed Action**

30
31 The purpose of the proposed action is to meet the Service’s management goal of protecting and
32 restoring the ecosystem of the Farallones, particularly seabirds and other native biological
33 resources, by eradicating non-native house mice.

34
35 The South Farallones have sustained ecological damage over many years from the presence of
36 mice. Prior to the introduction of non-native mammals, the
37 South Farallones provided seabirds with breeding and roosting
38 habitat and was nearly devoid of land-based predatory threats.
39 Introduced European rabbits (*Oryctolagus cuniculus*) and cats
40 (*Felis catus*), which were later removed, and mice, which
41 remain on the South Farallones today, have had noticeable
42 negative impacts on native species. Eradicating mice would
43 improve the breeding conditions and may increase the local
44 population size for at least two seabird species, the ashy storm-
45 petrel (*Oceanodroma homochroa*) and Leach’s storm-petrel
46 (*Oceanodroma leucorhoa*), and may also benefit other

Figure 1.1. Ashy storm-petrel

1. Purpose and Need

1 seabirds, as well as native amphibians, invertebrates, and plants. The ashy storm-petrel is a rare
2 species with a range limited almost entirely to California, with about half of the world's breeding
3 population occurring at the South Farallones. The South Farallones colony declined roughly 40%
4 between 1972-73 and 1992 (Sydeaman et al. 1998). The Leach's storm-petrel is a much more
5 widespread and numerous species with ~~a global range~~; however, in recent years it has also
6 declined in California (Carter et al. 1992). Data indicate the South Farallones colony has ~~actually~~
7 declined dramatically and may be close to extirpation (PRBO unpubl. data; G.J. McChesney
8 pers. comm.).

1.3. Need for Action

1.3.1. Summary of House Mouse Impacts on the South Farallon Islands

15 The Farallon National Wildlife Refuge, which originally encompassed the North and Middle
16 Farallon Islands and Noonday Rock, but did not include the South Farallones, was established by
17 President Theodore Roosevelt under Executive Order 1043 in 1909 as a preserve and breeding
18 ground for marine birds. In 1969 the Refuge was expanded to include the South Farallones and is
19 still managed with the same basic purpose today. Introduced ~~non-native~~ mice are directly and
20 indirectly negatively impacting the populations of small burrow- and crevice-nesting seabirds on
21 the South Farallones, particularly storm-petrels. In order to reduce this impact the Service has
22 identified mouse eradication as an important step in fulfilling its main purpose to protect and
23 restore the native ecosystems of the Farallone Islands.

25 Researchers have discovered that mice are indirectly responsible for extensive ashy storm-petrel
26 predation by burrowing owls (*Athene cunicularia*) that winter on the islands (Mills 2006) (PRBO
27 unpubl. data). The physical and behavioral similarities between ashy storm-petrels and Leach's
28 storm-petrels have led researchers to suspect that Leach's storm-petrels ~~are~~ suffering similar
29 predation. Burrowing owls are not considered island residents, but each year dispersing or
30 migrating burrowing owls land on the South Farallones to rest before returning to the mainland
31 (DeSante and Ainley 1980). The "accidental" arrival of migrating or dispersing landbirds onto
32 the Farallones is actually quite common; over 400 different landbird species have been recorded
33 on the islands since 1968 (Richardson et al. 2003). Most landbirds that arrive on the Farallones
34 return to the mainland within a few days (DeSante and Ainley 1980). However, some burrowing
35 owls arriving to the South Farallones stay on the islands and subsist largely on mice during the

Figure 1.2. Ashy storm-petrel remains beneath burrowing owl roost.

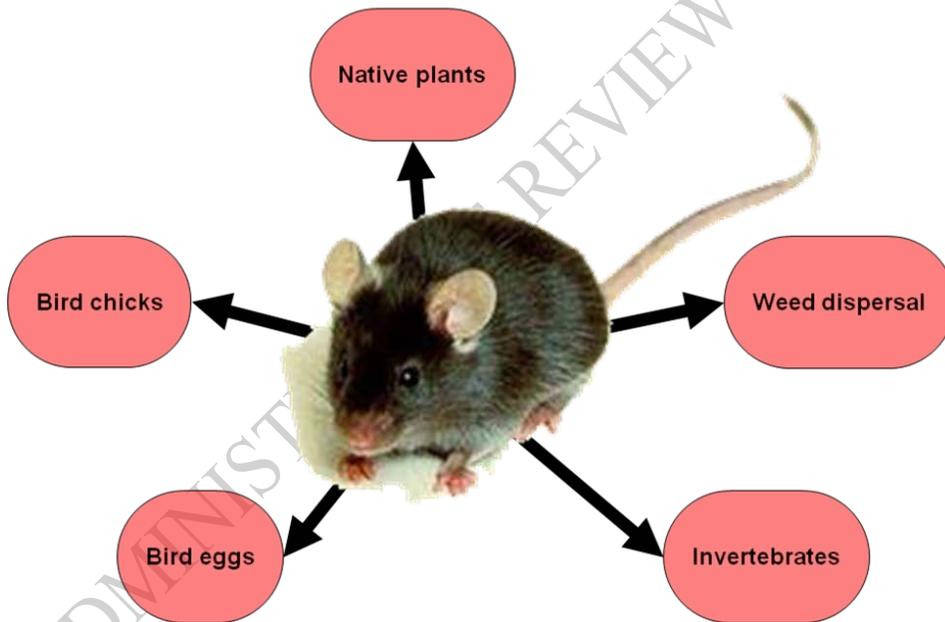

36 fall, when the mouse population is at an annual
37 peak. Between December and January, the mouse
38 population begins to plummet (a cyclical
39 counterpart to its fall peak) rendering mice
40 essentially unavailable to burrowing owls as a
41 food source by spring. As a result, the wintering
42 burrowing owls must switch to alternative prey
43 sources. Adult storm-petrels, which arrive on the
44 islands starting in mid-winter to visit breeding
45 sites and engage in courtship activity, are
46 susceptible to depredation by burrowing owls

Comment [g1]: Do we have a reference for this?

1. Purpose and Need

1 searching for alternative prey. Predation by owls is known to account for substantial annual
2 mortality of the ashy storm-petrel population, which has ~~recently undergone~~ a precipitous decline
3 at the South Farallones (Sydeman et al. 1998). In addition, owl predation is thought to threaten
4 Leach's storm-petrels on the Farallones ~~as well~~. Ultimately, the owls' switch in prey is ~~often~~
5 insufficient to sustain them through the winter. ~~The majority~~ of owls that ~~are~~ monitored on the
6 island through the winter do not survive, which researchers believe is related at least in part to
7 food scarcity, as well as fatal attacks by territorial western gulls (*Larus occidentalis*) that
8 dominate the islands by spring.

Impacts of House Mice

12 In addition to their indirect contribution to owl predation on storm-petrels, mice also may
13 directly impact storm-petrels through egg predation and disturbance ~~to burrows~~. The
14 inconspicuous nest sites of these small seabirds makes observation difficult and evidence of
15 mouse predation and disturbance on the South Farallones scarce. However, on other islands
16 similar to the Farallones throughout the world, mice have been documented preying on seabird

1. Purpose and Need

1 eggs and chicks (Cuthbert and Hilton 2004, Wanless et al. 2007, Angel et al. 2009). A more
2 detailed discussion of the impacts of mice to storm-petrels may be found in Section 4.4.3.3.1.

3
4 Evidence from other islands indicates that mice may have major impacts on invertebrates, plants,
5 and the endemic ~~an organism that exists~~ nowhere else on Earth, arboreal salamander subspecies
6 (*Aneides lugubris farallonensis*) on the Farallon Islands. Mouse diet analysis on the South
7 Farallones has shown that mice frequently consume native invertebrates and plants, including the
8 ecologically important maritime goldfields (*Lasthenia maritima*), a California native daisy
9 species (Jones and Golightly 2006). Furthermore, invertebrates and plants play a critical
10 structural role on the ecosystems of the South Farallon Islands, and any major direct impacts
11 from mice on these organisms have the potential to severely affect other aspects of the ecosystem
12 and may severely affect the future diversity of these islands.

13
14 More detailed discussions of the potential impacts of mice to invertebrates, plants, and
15 salamanders may be found in Sections 4.4.3.2.2-3 and 4.4.3.4.

18 1.3.2. Past Actions on the South Farallones

19
20 To reduce the rate of burrowing owl predation on storm-petrels, the Service has explored the
21 option of owl capture and translocation to sites on the mainland. However, attempts to capture
22 burrowing owls on the Farallones have proven only partially successful and very time-
23 consuming, especially when mice are abundant on the island and owls are consequently
24 unresponsive to baited traps (J. Barclay pers. comm.). Additionally, a burrowing owl
25 translocation program would have to continue in perpetuity in order to contribute meaningfully
26 to storm-petrel habitat improvement. Finally, burrowing owl translocation would not address the
27 other likely impacts of mice on the island ecosystem. While burrowing owl translocation may
28 temporarily reduce predation on storm-petrels in the short term, it cannot alone fulfill the
29 ecosystem-wide restoration objective identified as the purpose of action.

30
31 Western gulls, which nest on the South Farallones in large numbers, are also responsible for
32 substantial storm-petrel mortality due to both predation on storm-petrels and attacks on storm-
33 petrels that encroach on gull nesting territories. In the early 1970s on Southeast Farallon Island,
34 western gull breeding distribution was limited mainly to the island's broad marine terrace, which
35 is outside the principal talus slope breeding habitat of storm-petrels (Ainley and Lewis 1974).
36 Since that time, the South Farallones western gull colony has spread to nearly the entire island
37 group, including important storm-petrel breeding areas. The Service has, with limited success,
38 explored options for reducing the number of western gulls nesting in habitat critical to storm-
39 petrels and other small seabirds. These options have included installing wire grids over breeding
40 plots in an attempt to exclude predatory gulls. Additionally, the Service has considered the
41 possibility of targeted lethal control of gulls that have been observed to specialize in preying on
42 small seabirds including storm-petrels. While ~~options for reducing the gull population~~
43 Farallones may be appropriate as short-term actions ~~that might provide~~ mitigation for the high
44 predation rates of storm-petrels by gulls; ~~however, gull control~~ without mouse eradication would
45 not entirely fulfill the ecosystem-wide restoration objective identified as the purpose of action.

1. Purpose and Need

1 In addition, the Service conducts its ongoing management activities with special consideration
2 for protecting and enhancing seabird nesting habitat on the South Farallones, particularly for
3 crevice- and burrow-nesting species such as ashy and Leach's storm-petrels. For example, on
4 Southeast Farallon Island a "habitat sculpture" for crevice-nesting seabirds was recently built,
5 and crevices suitable for storm-petrel or auklet nesting were deliberately placed within recently
6 rebuilt rock walls (Ainley and Lewis 1974). The Service may conduct restoration projects in the
7 future that are designed specifically to enhance nesting habitat, such as the construction of
8 artificial nests or nesting structures. Further enhancement of storm-petrel nesting habitat, without
9 mouse eradication, would contribute partly towards the seabird restoration component of the
10 South Farallon Islands' restoration needs, but benefits would be limited if the current levels of
11 large scale adult storm-petrel mortality continues. In addition, these taxon-specific habitat
12 enhancements would not fulfill the ecosystem-wide restoration objective identified as the
13 purpose of action.
14
15

1.3.3. Benefits of House Mouse Eradication

16
17
18 The best scientific evidence available to the Service indicates that if mice are eradicated from the
19 South Farallones, migrant burrowing owls that arrive on the island in the fall would not remain
20 over the winter and would be unlikely to survive if they attempt to stay. Studies conducted on
21 seasonal fluctuations in owl diet have lent support to the hypothesis that owls depend on mice for
22 survival on the Farallones during the fall (Mills 2006). Furthermore, there have been no
23 confirmed accounts, current or historical, of burrowing owls successfully breeding on the islands
24 (DeSante and Ainley 1980), indicating the unsuitability of the Farallones environment for
25 resident burrowing owls.
26

27 While ashy storm-petrels are present in at least low numbers year-round, neither ashy nor
28 Leach's storm-petrels are common on the South Farallones until their pre-breeding burrow visits
29 begin around February (Ainley and Lewis 1974, Ainley et al. 1990a). On the other hand, two
30 decades of data show that burrowing owls are much more likely to arrive on the South Farallones
31 in the fall and early winter than in any other season (Richardson et al. 2003). Therefore, it is
32 highly probable that if mice are removed from the South Farallones, then owls that arrive on the
33 islands would behave similar to the thousands of other birds that are accidental to the islands
34 each fall and stay no more than a few days. Thus, storm-petrels would no longer be at risk of
35 predation by owls when they arrive later in the winter.
36

37 Mouse eradication may also lead to a noticeable increase in invertebrate populations (Newman
38 1994, Ruscoe 2001). This was the case on Mana Island, for example, where populations of the
39 Cook Strait giant weta *Deinacrida rugosa*, an insect native to New Zealand that is similar to a
40 giant grasshopper, increased noticeably after mouse eradication (Newman 1994).
41

42 The eradication of mice on the South Farallones will likely benefit the island's native salamander
43 by removing the predation pressure on salamanders from mice and eliminating the competition
44 between salamanders and mice for insects. Both of these benefits will likely have a positive
45 impact on the salamander's island population. After a successful mouse eradication on Mana
46 Island in New Zealand, the populations of McGregor's skinks (*Cyclodina macgregori*) and

1. Purpose and Need

1 common geckos (*Hoplodactylus maculatus*) increased substantially; both of these species were
2 under similar pressures from mice as the Farallones' salamanders are today (Newman 1994).

3 More discussion of the benefits of mouse eradication may be found in Section 4.4.6.

4 **1.3.4. Background: The Problem of Introduced Species on Islands**

6 *1.3.4.1. Introduced species and the importance of island ecosystems*

8 It is widely accepted that the natural world is currently facing a particularly high rate of species
9 extinction (Raup 1988), that most recent extinctions can be directly attributed to human activity
10 (Diamond 1989), and that for ethical, cultural, aesthetic, and economic reasons, this current rate
11 of extinction is cause for considerable concern (Ehrlich 1988, Ledec and Goodland 1988). One
12 of the major worldwide causes of anthropogenic extinctions is the introduction of non-native
13 species. Introduced species are responsible for 39 percent of all of the recorded animal
14 extinctions since 1600 for which a cause could be attributed (World Conservation Monitoring
15 Centre 1992).

17 Island ecosystems are key areas for biodiversity conservation worldwide. While islands make up
18 only about 3 percent of the earth's surface, they are home to 15-20 percent of all plant, reptile,
19 and bird species (Whittaker 1998). However, small population sizes and limited habitat
20 availability make species endemic to islands especially vulnerable to extinction, and their
21 adaptation to isolated environments makes them particularly vulnerable to aggressive introduced
22 species (Diamond 1985, 1989, Olson 1989). Of the 484 recorded animal species extinctions since
23 1600, 75 percent were species endemic to islands (World Conservation Monitoring Centre 1992).
24 Introduced species were at least partially responsible for a minimum of 67 percent of these
25 island extinctions (based on the 147 island species for which the cause of extinction is known,
26 calculated from World Conservation Monitoring Centre 1992).

28 Islands are high-value targets for conserving biodiversity because:

- 29 1. A large percentage of their biota are endemic species and subspecies with small
30 populations, which makes them particularly extinction-prone (Darwin 1859, Elton 2000).
- 31 2. They are critical habitat for seabirds and pinnipeds, which feed over thousands of square
32 kilometers of ocean but are dependent on small isolated islands for safe breeding.
33 Protection of these animals at their island breeding sites is easier and more cost-effective
34 than protecting them from threats at sea (such as plastics pollution and accidental or
35 deliberate entanglement in fishing tackle), which could affect them anywhere along their
36 travels (Wilcox and Donlan 2007).
- 37 3. Many islands are sparsely inhabited or uninhabited by humans, keeping the
38 socioeconomic costs of protection low.

40 *1.3.4.2. Non-native house mice*

42 The house mouse, which originated in Southeast Asia, is now among the most widespread of all
43 mammals, a result of its close association with humans and the relative ease with which it can be
44 transported and introduced to new locations. House mice are present on at least 64 island groups
45 in all of the world's major oceans (Atkinson 1989). They are among the vertebrates considered to
46 be "significant invasive species" on islands of the South Pacific and Hawaii, officially reported
47 from 41 islands but having probably reached all inhabited islands in the Pacific and numerous

1. Purpose and Need

1 uninhabited islands (Atkinson and Atkinson 2000). The resourcefulness of house mice is evident
2 from their global distribution and their broad habitat range including buildings, agricultural land,
3 coastal regions, grasslands, salt marshes, deserts, forests and subantarctic areas (Efford et al.
4 1988, Triggs 1991, Atkinson and Atkinson 2000).

6 1.3.4.3. Impacts of non-native house mice on island ecosystems

8 House mice are omnivorous species that eat a variety of seeds, fungi, insects, reptiles, other
9 small animals, and the eggs of small birds. In addition, they are known to have dramatic negative
10 impacts on endemic arthropods (Rowe-Rowe et al. 1989, Cole et al. 2000).

12 This direct impact on arthropods in turn has the potential to extend throughout the ecosystem, as
13 arthropods are often crucial in the pollination and seed dispersal strategies of plants, the
14 decomposition of dead plant and animal matter, and as a food resource for other native species.
15 On Marion Island in the southern Indian Ocean, for example, house mice are substantially
16 affecting the populations of a number of endemic invertebrates, especially the Marion flightless
17 moth (*Pringleophaga marioni*), the single most important decomposer on the island.
18 Furthermore, house mice may be affecting the amount of food available for the native
19 insectivorous species, the lesser sheathbill (*Chionis minor*). Lesser sheathbill flocks on Marion
20 Island are much smaller than those on nearby, mouse-free Prince Edward Island, suggesting that
21 food competition from house mice is negatively affecting Marion's lesser sheathbill population
22 (Rowe-Rowe et al. 1989, Crafford 1990). Also on Marion Island, mice have significantly altered
23 the vegetation community through seed predation, showing a preference for native plants over
24 introduced ones (Angel et al. 2009).

26 House mice can also have a substantial negative impact to native reptiles and amphibians on
27 islands. On Mana Island in New Zealand, for example, Newman (1994) found mice were a major
28 contributing factor in the population collapse of the island's rare McGregor's skink (*Cyclodina*
29 *macgregori*). After successful mouse eradication, the population of McGregor's skink, the gecko
30 (*Hoplodactylus maculates*) and the endemic giant cricket (*Deinacrida rugosa*) increased
31 significantly.

33 One of the more surprising effects of mice on
34 islands is their negative impact to seabird and
35 native landbird populations through direct
36 predation on eggs and chicks, especially when
37 mice are the only non-native mammal present
38 (Angel et al. 2009). On Gough Island in the
39 southern Atlantic Ocean, introduced house
40 mice prey on chicks of the rare Tristan
41 albatross (*Diomedea dabbenena*), leading to an
42 unusually low breeding success rate of 27
43 percent in this declining seabird species
44 (Cuthbert and Hilton 2004). Furthermore, mice
45 on Gough Island appear to limit the breeding
46 range of the endemic Gough bunting (*Rowettia*
47 *goughensis*) to the small amount of mouse-free

Figure 1.3. A house mouse feeding on a seabird carcass on Gough Island.

1. Purpose and Need

1 habitat remaining on the island (Cuthbert and Hilton 2004). Similarly, on Marion Island, where
2 the recent eradication of feral cats left mice as the only non-native mammal on the island,
3 researchers recorded several wandering albatross (*Diomedea exulans*) killed by mice subsequent
4 to cat removal (Wanless et al. 2007, Angel et al. 2009).

Comment [DG2]: Add calculation of kg/ha of island biomass consumed by mice per year

1.3.4.4. Hyperpredation on islands

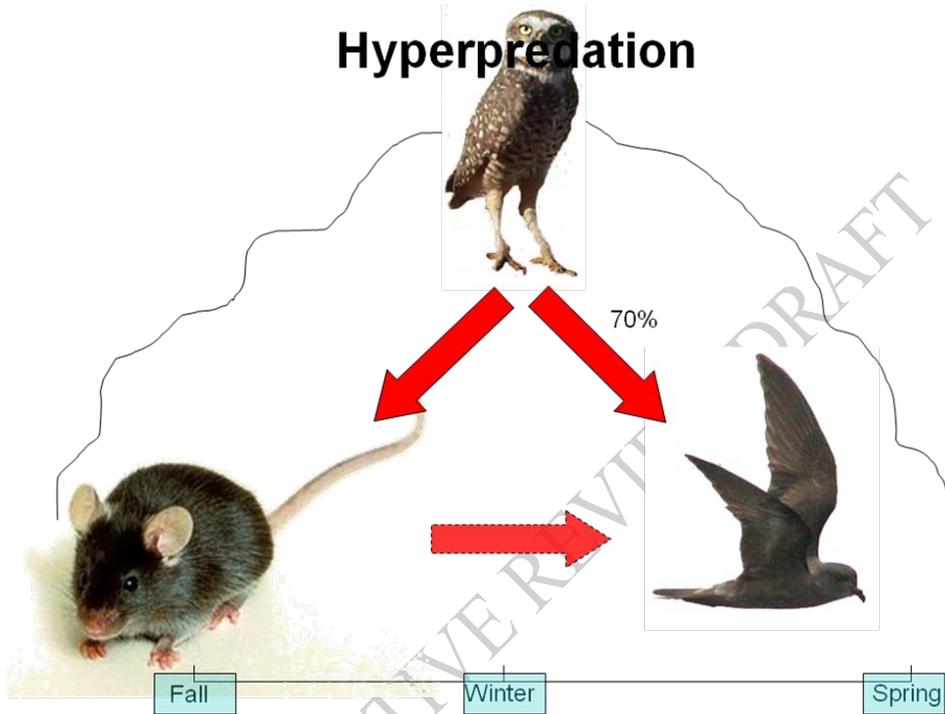

8 Hyperpredation refers to an enhanced level of predation pressure on a secondary prey species
9 due to an increase in the abundance of a predatory population or a sudden drop in the abundance
10 of the main prey item; this mechanism has been documented in cases where an introduction of a
11 non-native prey species causes the exploitation of native prey species (Holt 1977, Smith and Quin
12 1996, Moleón et al. 2008). The decline of ash storm-petrels and likely Leach's storm-petrels on
13 the South Farallones is partially driven by the interaction between burrowing owls and non-
14 native mice (as described in Section 1.3.1 above) and is a good example of the impact that
15 introduced species can have on an ecosystem through the mechanism of hyperpredation. A
16 number of similar examples, involving one or more non-native species that contribute to declines
17 in native island species, have recently been described. Allan's Cay in the Bahamas provides an
18 example that is similar to the current situation on the Farallones. Non-native mice on the island
19 are attracting much larger numbers of barn owls (*Tyto alba*) than other ecologically similar sites
20 in the region. Because owls also prey on the Audubon's shearwater (*Puffinus lherminieri*) that
21 has breeding colonies on many of the cays in the region, the shearwater population on Allan's
22 Cay is experiencing a mortality rate that is twice as high as on cays that are mouse-free. This
23 high mortality will likely contribute to the colony's extirpation in the future if conditions do not
24 change (W. Mackin pers. comm.).

26 Another example of hyperpredation comes from Santa Cruz Island in Channel Islands National
27 Park, southern California, where biologists found that golden eagles (*Aquila chrysaetos*) that
28 were sustained by non-native feral pigs (*Sus scrofa*) were occasionally switching their prey
29 preference to the endemic island fox (*Urocyon littoralis*). Eagle predation has played a major
30 role in the ongoing catastrophic decline of the fox (Roemer et al. 2001). Feral pigs were recently
31 eradicated from Santa Cruz Island, in hopes of breaking this cycle of predation and arresting the
32 many other negative impacts that feral pigs have had on the island's resources (Morrison et al.
33 2007). Biologists have seen a similar pattern on islands where feral cats maintain high population
34 densities between seabird breeding seasons because they are subsidized by introduced rodents
35 (Atkinson 1985) or rabbits (Apps 1983, Courchamp et al. 1999, 2000). In all of these examples,
36 the presence of a non-native prey animal led to substantial declines in native prey species
37 through opportunistic predation by a local predator that was sustained at artificially high
38 population levels.

40 Hyperpredation on the Farallones consists of a transient burrowing owl population that is being
41 subsidized by a non-native mouse population as a primary artificial food source in the fall and
42 winter, but with the depletion of the mice numbers in the late winter, the owls shift to preying on
43 petrels and other seabirds. If the mice were no longer present as a prey base, the owls would
44 likely resume their normal patterns and move on back to the mainland after a couple of days on
45 the island when they realize that very little prey occurs on the island. The figure below illustrates
46 the shift in prey base and how the mice artificially subsidizes the owl population on the island.

1.4. Authority and Responsibility to Act

The eradication of non-native house mice from the South Farallon Islands is authorized and in many cases mandated by several federal laws requiring land managers to conserve and restore wildlife and habitats under their jurisdiction.

The U.S. Fish and Wildlife Service's mission is to work with others to "conserve, protect and enhance fish, wildlife, and plants and their habitats for the continuing benefit of the American people." The threat that introduced species pose to habitat and native wildlife makes addressing their impacts one of the Service's top management priorities. Lessening or eliminating the impacts of introduced species on the Farallones is essential to the Service's management strategy for the islands.

The Fish and Wildlife Act of 1956 (16 U.S.C. 742a-742j, not including 742 d-1, 70 Stat. 1119), as amended, gives general guidance that can be construed to include alien species control, that requires the Secretary of the Interior to take steps "required for the development, management, advancement, conservation, and protection of fish and wildlife resources."

1. Purpose and Need

1 ***The National Wildlife Refuge System Administration Act of 1966 (NWRSA)*** (16 USC 668dd)
2 established the National Wildlife Refuge System, to be managed by the Service. Among other
3 mandates, the NWRSA requires the Service to provide for the conservation of fish, wildlife,
4 and plants, and their habitats within the System; and to ensure that the biological integrity,
5 diversity, and environmental health of the System are maintained.

6
7 ***The Endangered Species Act of 1973 (ESA)*** (16 U.S.C. 1531-1544, 87 Stat. 884), as amended,
8 directs the Service to conserve ecosystems upon which threatened and endangered species
9 depend.

10
11 ***The National Wildlife Refuge System Improvement Act of 1997 (NWRISA)***, which amends the
12 NWRSA, serves as an “Organic Act” for the Refuge System and provides comprehensive
13 legislation on how the Refuge System should be managed and used by the public. The NWRISA
14 clearly establishes that wildlife conservation is the singular Refuge System mission, provides
15 guidance to the Secretary of the Interior for management of the System, provides a mechanism
16 for refuge planning, and gives refuge managers uniform direction and procedures for making
17 decisions regarding wildlife conservation and uses of the System.

18
19 ***The USFWS policy for maintaining biological integrity and diversity and environmental***
20 ***health*** (601 FW 3, 2001), directs Refuges to “prevent the introduction of invasive species, detect
21 and control populations of invasive species, and provide for restoration of native species and
22 habitat conditions in invaded ecosystems.” 601 FW 3 further directs refuge managers to “develop
23 integrated pest management strategies that incorporate the most effective combination of
24 mechanical, chemical, biological, and cultural controls while considering the effects on
25 environmental health.”

26
27 ***The USFWS’s Regional Seabird Conservation Plan*** lists mouse eradication from the Farallones
28 as a top seabird conservation priority in the region.

29
30 ***Comprehensive Conservation Plan (CCP) for Farallon National Wildlife Refuge***. As mandated
31 by the NWRISA, the Service is preparing a CCP to guide future management actions on the
32 Refuge to meet the missions and purposes of the Refuge and the Service. The CCP includes
33 mouse eradication from the South Farallon Islands as an objective for the Refuge’s management
34 direction.

35
36 ***Presidential Executive Order 13112 on Invasive Species*** (February 3, 1999): Section 2(a)(2), on
37 Federal agency duties, states: “Each Federal agency whose actions may affect the status of
38 invasive species shall, to the extent practicable and permitted by law, subject to the availability
39 of appropriations, and within Administration budgetary limits, use relevant programs and
40 authorities to: (i) prevent the introduction of invasive species; (ii) detect and respond rapidly to
41 and control populations of such species in a cost-effective and environmentally sound manner;
42 (iii) monitor invasive species populations accurately and reliably; (iv) provide for restoration of
43 native species and habitat conditions in ecosystems that have been invaded; (v) conduct research
44 on invasive species and develop technologies to prevent introduction and provide for
45 environmentally sound control of invasive species; and (vi) promote public education on
46 invasive species and the means to address them.”

1. Purpose and Need

Executive Order 13112 defines “invasive species” as “an alien species [a species that is not native with respect to a particular ecosystem] whose introduction does or is likely to cause economic or environmental harm or harm to human health.”

1.5. Scope of the Proposed Action

The proposed action focuses on three areas:

1. Activities necessary to eradicate house mice from the South Farallones;
2. Activities necessary to prevent the reintroduction of house mice to the South Farallon Islands, and to prevent the new introduction of any terrestrial vertebrates to the Farallones in the future; and
3. Activities necessary to minimize negative impacts to native species and maintain wilderness values on the Farallones during the course of mouse eradication and reintroduction-prevention activities.

1.6. Environmental Issues (Impact Topics) Identified

1.6.1. Summary of Scoping

Section 1501.7 of the CEQ regulations for implementing NEPA requires that agencies implement a process, referred to as “scoping”, to determine the scope of issues to be addressed in an environmental impacts analysis and identify the major environmental issues related to a proposed action that need to be analyzed. The scoping process included research in published and unpublished literature, consultations with experts in the ecology of the Farallones and experts in non-native species eradication, consultation with the government agencies that have a stake in the resources of the Farallones and adjacent waters, and invitations for comments from the public. There is a detailed description of the scoping process that the Service conducted for this EA in Chapter 5. During the scoping process, the Service identified the major environmental issues, or “impact topics,” that are described in Sections 1.6.2-1.6.4 below. These issues guided the development of the alternatives in chapter 2, and the scope and content of the environmental impacts analysis for each alternative found in Chapter 4.

1.6.2. Impact Topic: Physical Resources

1.6.2.1. Sub-topic: Impacts to water resources

Because the proposed action includes the delivery of a toxicant into the Farallones environment, the potential impacts of the toxicant to local water quality was identified as an important environmental issue.

1.6.2.2. Sub-topic: Impacts to geology and soils

1. Purpose and Need

1 Because the proposed action includes delivery of a toxicant into the Farallones environment, the
2 potential for transfer and persistence of the toxicant in soils was identified as an important
3 environmental issue.

1.6.2.3. Sub-topic: Impacts to wilderness character

7 All of the South Farallones except Southeast Farallon Island are designated as wilderness under
8 the Wilderness Act of 1964 (PL 88-577). Wilderness designation makes the wilderness character
9 of the South Farallones an important environmental issue.

1.6.3. Impact Topic: Biological Resources

1.6.3.1. Sub-topic: Non-target impacts from toxicant use

16 Mouse eradication would include the use of a toxicant that is lethal to mice. Toxicants should
17 only be used in the environment if the behavior of that toxicant can be predicted with some
18 accuracy. The impact of the toxicant to species other than mice and the persistence of the
19 toxicant in the environment are important environmental issues related to the impacts of the
20 action to biological resources, because animals other than mice, including birds, could ingest the
21 toxicant.

1.6.3.2. Sub-topic: Disturbance to sensitive species

25 Similar to most other oceanic islands, the Farallones are important habitat for species, such as
26 seabirds and pinnipeds, that are especially sensitive to disturbance. The risk of disturbance to
27 sensitive species from the proposed action is an important environmental issue related to the
28 impacts of the action to biological resources, particularly because of the importance of the
29 islands for breeding seabirds and pinnipeds.

1.6.4. Impact Topic: Social and Economic Environment

1.6.4.1. Sub-topic: Impacts to Refuge visitors and recreation

36 The Farallones are closed to the public to protect the Refuge's sensitive biological resources, but
37 the animal species that depend on the Farallones are nevertheless important resources for wildlife
38 enthusiasts visiting the nearshore waters and throughout these species' ranges. Additionally,
39 recreational boaters utilize the marine region surrounding the islands. Finally, a small number of
40 FWS and PRBO personnel, contractors, and visiting researchers utilize the island year-round.

1.6.4.2. Sub-topic: Impacts to fishing resources

44 The waters surrounding the Farallones are important recreational and commercial fishing
45 grounds for species such as salmon, albacore tuna (*Thunnus alalunga*), Dungeness crab
46 (*Metacarcinus magister*), halibut, and rockfish (Scholz and Steinback 2006). The State of
47 California, as mandated by the State's Marine Life Protection Act, is in the process of

Comment [g3]: Identify the species

1. Purpose and Need

1 establishing the Southeast Farallon Island Marine Reserve surrounding the South Farallon
2 Islands. ~~Fishing will be~~ prohibited within the Marine Reserve.

Comment [g4]: Check the status marine reserve? What does that do to fishing?

3
4 1.6.4.3. Sub-topic: Impacts to historical and cultural resources

5
6 The impact of the action to historical and cultural sites, structures, objects and artifacts on the
7 South Farallones are important environmental issues.

ADMINISTRATIVE REVIEW DRAFT

Chapter 2 Alternatives

2.1 Introduction to the Development of Alternatives

As part of the analytical process mandated by NEPA, section 102(2)(E) requires all Federal agencies to “study, develop, and describe appropriate alternatives to recommended courses of action in any proposal which involves unresolved conflicts concerning alternative uses of available resources.” Based upon the existing site conditions, need for action, constraints and the public concerns identified during the public scoping process, 4 alternatives were identified: 3 action alternatives (Alternative B-D) and the no action alternative (Alternative A), which is included in NEPA analysis to provide a benchmark with which to compare the magnitude of environmental effects of the action alternatives. The no action alternative will describe the Service’s current management regime on the South Farallones with regard to the mouse population and its impacts to the island ecosystem.

The action alternatives were developed to focus on the issues identified by resource specialists within the Service, experts in island rodent eradication, government regulatory agencies, and the general public. All individuals, agencies and organizations that provided substantive input regarding the proposed action are listed in Chapter 5.

A number of additional alternatives were initially considered but rejected. In order to be retained for consideration, an alternative had to 1) have a high likelihood of success, 2) have an acceptably low probability for adverse effects on non-target species and the environment, and 3) be permitted under existing regulations governing the Refuge.

The alternatives are:

- *Alternative A: No Action*
- *Alternative B: Aerial broadcast*
- *Alternative C: Bait stations as primary method of bait delivery*
- *Alternative D: Phased aerial broadcast with extensive use of gull-hazing measures*

A number of action alternatives that were dismissed from detailed consideration are also described, and rationale for their dismissal is given (Section 2.8).

2.2 Alternative A: No Action

Analysis of the no action alternative is required under NEPA to provide a benchmark to compare the action alternatives to. Mice would not be eradicated under this alternative; however, other ongoing invasive species management programs on the South Farallones would continue based on previous agency decisions. Low-intensity mouse control – primarily snap-trapping – currently occurs within and around the residences and buildings on Southeast Farallon Island. These

Comment [DG5]: We should discuss whether This should be moved to Section 2.8 (Dismissed) due to lower likelihood of success

2. Alternatives

1 localized control efforts would continue under the no action alternative, but the mouse
2 population on the rest of the South Farallones would not be subject to control efforts. The
3 Service currently removes invasive plants through hand-pulling and herbicide applications.
4 Additionally, native plant seeds are being spread to improve native populations and encourage
5 the suppression of non-natives. Finally, vegetation on the islands is being closely monitored to
6 allow for quick response to new invaders or spreading populations of current pests. These efforts
7 would continue under the no action alternative. However, the continued presence and impacts of
8 mice might compromise the effectiveness of future ecosystem restoration efforts.

9
10 The Service would also continue management activities focused on protecting storm-petrels and
11 their habitat on the islands, including nest habitat construction and predator management. Prior
12 to Fall 2008, the Service occasionally relocated burrowing owls that were overwintering on the
13 island to protect storm-petrels from predation. The Service did not relocate any owls in 2008 to
14 allow researchers to collect additional data on owl movement patterns. Under the no action
15 alternative, the Service would continue to relocate burrowing owls whenever possible.
16 Additionally, because western gulls are likely the most common resident predator of storm-
17 petrels on the Farallones, there have been efforts in the past to deter gulls from nesting in prime
18 storm-petrel habitat, but these efforts have been unsuccessful to date. The Service is considering
19 the possibility for targeted control of gulls that specialize in preying on storm-petrels and would
20 continue to consider this possibility under the no action alternative.

21
22 The current rodent introduction-prevention protocols for vessels that transport personnel and
23 materials to Southeast Farallon Island would continue under the no action alternative. However,
24 these protocols are not always enforced, leaving the islands at risk of invasion by other species of
25 rodents such as rats, or additional introductions of mice.

26
27 Taking no action to address the effects of non-native mice would be contrary to the purpose of
28 the refuge and other USFWS policies for conservation and restoration of natural biodiversity and
29 management of designated wilderness.

2.3 Features Common to All Action Alternatives

30
31
32
33
34
35 All three action alternatives will necessarily involve the use of brodifacoum delivery by both bait
36 stations as well as by aerial broadcast, and all three have many other features in common as well.
37 These features are described below.

2.3.1 Use of Techniques with High Likelihood of Successful Eradication

38
39
40
41 The overarching technical goal in a successful rodent eradication is to ensure the delivery of a
42 lethal dose of toxicant to every rodent on the island. The objective of eradication is unique within
43 the field of pest management because 100 percent of the target population must be made
44 vulnerable. Eradication is a more complex objective than the much more common goal of
45 “control,” in which managers aim primarily to reduce a target population to acceptably low

2. Alternatives

1 numbers. The Service considered mouse “control” rather than eradication but dismissed it from
2 detailed consideration (see Section 2.9.7).

3
4 The high cost and high complexity of non-native mouse eradication from the South Farallones
5 make success especially critical. The established record of successes (as well as failures) in the
6 nearly 30 previous island mouse eradication attempts across the globe indicates that, if
7 implemented carefully and correctly, the action alternative methods proposed would have a high
8 likelihood of successfully eradicating mice (Witmer and Jojola 2006, Howald et al. 2007a).

Comment [DG6]: Need to discuss likelihood of success using Alternative C (bait stations)

11 2.3.2 Use of the Rodenticide Brodifacoum

12
13 Brodifacoum (3-[3-(4'-bromobiphenyl-4-yl)-1,2,3,4-tetrahydro-1-naphthyl]-4 hydroxycoumarin)
14 is a coumarin-based anticoagulant rodenticide. Anticoagulant rodenticides are the most widely
15 used toxicant for control of small mammals worldwide (Eason et al. 2002, Hoare and Hare 2006,
16 Howald et al. 2007b). They act by inhibiting the synthesis of vitamin-K-dependent clotting
17 agents in the liver, interfering with the blood's ability to form clots and causing sites of even
18 minor tissue damage to bleed continuously (Hadler and Shadbolt 1975, Eason and Ogilvie 2009).
19 Mortality from anticoagulant rodenticides is caused by internal hemorrhaging, typically within 3-
20 10 days of initial consumption (Buckle and Smith 1994, Howald et al. 2007b, Eason and Ogilvie
21 2009). It is a vertebrate toxicant that acts by interfering with the blood's ability to form clots,
22 causing sites of even minor tissue damage to bleed continuously.

23
24 Brodifacoum is the most commonly-used rodenticide in the United States (Erickson and Urban
25 2004a). Its use is restricted to professional pest control operations (72 FR 10 pp. 1992-3, 2007).
26 It would be used according to Environmental Protection Agency (EPA) approved pesticide label
27 instructions, which define the legally allowable uses and restrictions of the specific pesticide
28 under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA). All bait application
29 activities will be conducted under the supervision of a Pesticide Applicator certified by the EPA.
30 Brodifacoum is also the most extensively utilized and best-understood rodenticide for rodent
31 eradication from islands – out of the 332 known island rodent eradication efforts worldwide
32 reported as successful, 71 percent of them used brodifacoum (Howald et al. 2007a).

33
34 In order for the toxicant to have physical effects, brodifacoum levels in the liver must reach a
35 toxic threshold; this level can vary widely between species and even between individuals. The
36 relative threshold level for mice to experience toxic effects from brodifacoum exposure is very
37 low, but for other vertebrate species the threshold level is much higher. In other words, some
38 vertebrates can consume large amounts of brodifacoum before experiencing physical symptoms
39 of toxicity.

40
41 Pressed-grain bait pellets (1 g – 2 g) containing a rodenticide will be applied at a rate that is
42 expected to successfully eradicate mice from the treatment area according to Environmental
43 Protection Agency (EPA) approved pesticide label instructions, which define the legally
44 allowable uses and restrictions of the specific pesticide. All bait application activities will be
45 conducted under the supervision of a Pesticide Applicator certified by the U.S. EPA.

46

2. Alternatives

1 Anticoagulants are classified as first or second-generation according to when they were first
2 developed as rodenticides and, consequently, their toxicity (Eason et al. 2002). First-generation
3 anticoagulants, which include diphacinone, generally appear to be most effective at achieving
4 mortality in rodents when consumed over several consecutive days, although a single high dose
5 may be toxic to some animals (Eason and Ogilvie 2009). Second-generation anticoagulants are
6 more toxic than first-generation, with lower LD₅₀ values (median lethal dose, or the amount
7 required to kill 50 percent of a test population), and are typically ‘single feed’ poisons in high
8 enough concentrations (Hone and Mulligan 1982) in (Eason and Ogilvie 2009). The generally
9 lower toxicity of first-generation anticoagulants compared to second-generation products is
10 attributed to their poorer binding affinity to sites in the liver. Second-generation anticoagulants
11 have a greater binding affinity than first-generation anticoagulants, which increases the rate of
12 metabolism, requiring only one feeding to be effective (Parmar et al. 1987). In order for either
13 toxicant to have physiological effects, levels in the liver must reach a toxic threshold; this level
14 can vary widely between species and even between individuals within a species. But any
15 rodenticide can kill all of a rat population if the animals consume enough bait over an
16 appropriate amount of time.

17
18 Brodifacoum-25D™ Conservation is manufactured by Bell Laboratories (Madison, WI, EPA
19 Reg. No. 56228-37) specifically for use on island invasive situations in dry climates. The bait
20 product is designed to be highly attractive to rodents, such that rodents on the island are more
21 likely to choose the bait over natural food sources. The predominant inactive ingredients in these
22 bait products are non-germinating grains, either sterile or crushed. It is a “restricted use
23 pesticide” according to the EPA-approved pesticide label developed for each product:

- The product may only be used on islands or vessels [marine is implied]
- The product may only be used for the control or eradication of invasive rodents.
- The product is only available for sale to 3 federal government agencies: USDA/APHIS, Wildlife Services, U.S. Fish and Wildlife Service, and U.S. National Park Service, although these agencies can make the bait available to other agencies or private parties under their oversight.
- The product may only be applied by Certified Pesticide Applicators (a certification generally provided by the State or Territory in which the bait is to be applied) or persons under their direct supervision.

34 *Brodifacoum-25D™ bait product*

35 Brodifacoum is the most frequently used rodenticide for rodent eradication from islands. Of the
36 278 successful island rodent eradication events worldwide (where the toxicant applied was
37 known), 197 (71 percent) used brodifacoum as the primary rodenticide (Howald et al. 2007b),
38 Island Conservation unpubl. data). In 92 (47 percent) occasions bait stations were the primary
39 technique used to deliver brodifacoum, 58 (29 percent) occasions used aerial broadcast as the
40 primary technique, and 43 (21 percent) occasions used hand-broadcast as the primary technique.
41 Of these, in 33 (17 percent) occasions, a combination of bait stations, hand-broadcast, aerial
42 broadcast, and/or traps were used, the most common of which was aerial broadcast as the
43 primary technique supplemented with hand-broadcast (14 or 7 percent of occasions) (Howald et
44 al. 2007b), Island Conservation unpub. data).

Comment [DG7]: Confirm #

2. Alternatives

1 Brodifacoum is highly toxic to mice requiring the consumption of no more than a single bait
2 pellet as a single feed or spread across multiple feeding events to result in mortality (Erickson
3 and Urban 2004b, Eason and Ogilvie 2009). The LD₅₀ dose has been achieved in Norway rats
4 ingesting 1.5 g (0.052 oz) of brodifacoum bait product in a single feeding (0.3 mg/kg at 50 ppm
5 brodifacoum) (Buckle and Smith 1994). The toxicity of brodifacoum to mice makes it desirable
6 as a tool for rat eradication because it reduces the need to make bait consistently available to rats
7 for an extended period of time.
8

Comment [DG8]: Review for mice LD50

Comment [DG9]: Add mouse LD50 citations

9 Brodifacoum-25D Conservation™ (hereafter referred to as Brodifacoum-25D™) is an unwaxed
10 cereal bait product with 25 ppm brodifacoum, available in 1g-3g pellets with a sweet, grain
11 flavor. The product is manufactured specifically for conservation purposes; Brodifacoum-25D™
12 is for use in dry climates and is designed to break down quickly after exposure to moisture,
13 including both dew and rainfall.
14

15 Brodifacoum-25 ppm products (Bell Laboratories, Madison, WI) have been used to successfully
16 eradicate rats from at least 5 islands using aerial broadcast as the primary technique (Samaniego-
17 Herrera et al. 2009, Buckelew et al. 2010, Howald et al. 2010), and from one island using hand-
18 broadcast (Hall et al. 2006). In addition, the bait product has been tested for efficacy and
19 palatability under laboratory conditions, prior to their use in eradication operations. To
20 successfully eradicate rodents from an island, every rodent must be exposed to sufficient
21 quantities of rodenticide, by either consuming bait or eating other animals that have consumed
22 bait, to acquire a lethal dose of brodifacoum. A bait trial must similarly demonstrate that
23 100percent of the rodents in the trial area were lethally exposed to bait. Brodifacoum-25
24 products (Bell Labs, Madison, WI) have also been tested with favorable results in at least 3 field
25 sites: the Aleutian Islands in Alaska (Buckelew et al. 2008b), Palmyra Atoll in the equatorial
26 Pacific (Buckelew et al. 2005b), and Pohnpei, Micronesia in the western Pacific (Wegmann et al.
27 2007).
28

29 During field trials, brodifacoum has been shown to be more palatable to rats in comparison to
30 naturally-available food sources (Buckelew et al. 2005b, Buckelew et al. 2008b, Alifano and
31 Wegmann 2010). The palatability of Brodifacoum-25 to rats makes it a desirable tool for mouse
32 eradication because it increases the probability that every mouse on the island will consume bait.
33

34 While high toxicity and high palatability are desirable bait characteristics from the perspective of
35 successfully eradicating rats, these same characteristics can be undesirable from the perspective
36 of minimizing non-target impacts (Hoare and Hare 2006). Brodifacoum is highly toxic to many
37 birds (Erickson and Urban 2004b), and can be toxic to secondary consumers that prey on primary
38 bait consumers (Rammell et al. 1984, Dowding et al. 1999, Stone et al. 1999). Furthermore,
39 because brodifacoum can persist in body tissues of vertebrate and invertebrate species, potential
40 non-target impacts from brodifacoum through secondary exposure of predators, has been shown
41 to be extended beyond the period of time that bait pellets themselves are available in the
42 environment (Eason et al. 2002, Fisher et al. 2004). The pellets are manufactured with a grain
43 base to be attractive as a food item to rodents, but the pellets are also likely attractive to other
44 granivorous and opportunistic omnivorous animals. However, other species such as insectivores
45 (some landbirds, shorebirds, reptiles), herbivores (e.g. fruit-eating pigeons), and carnivores (e.g.
46 fish-eating seabirds) would be unlikely to identify the pellets as a food item, would not be as

2. Alternatives

1 attracted to the pellets as food, and thus would be unlikely to intentionally consume them as
2 food. Additionally, pellets would be dyed green which has been shown to make pellets less
3 attractive to some birds and reptiles (Pank 1976a, Tershy et al. 1992a, Tershy and Breese 1994a).
4 Despite this, mortality in individual non-target birds during several rat eradication operations
5 have been attributed to brodifacoum bait products that were used for the eradications (Eason and
6 Spurr 1995, Eason et al. 2002, Buckelew et al. 2005b, Buckelew et al. 2010).

Figure 2.2 Bait pellet after exposure to moisture.

11 In an effort to reduce risks to wildlife and people but allow rodenticide products to remain
12 available, the EPA recently limited the use of brodifacoum and 9 other rodenticides;
13 brodifacoum is currently restricted to agricultural applications, professional pest control
14 operations, and ecosystem restoration efforts on islands (Environmental Protection Agency
15 2008). However, the EPA does not discourage the use of brodifacoum for rodent eradication
16 from islands. On the contrary, the EPA's recent decision to restrict brodifacoum use explicitly
17 exempted its use for island rodent eradication (Environmental Protection Agency 2008). In
18 addition, the New Zealand Department of Conservation identifies brodifacoum as the preferred
19 toxicant for island rodent eradication (Eason and Ogilvie 2009). These explicit exemptions are
20 logical in light of the fact that island rodent eradication operations are fundamentally different
21 from rodent control operations. The potential risks from using brodifacoum for eradication can
22 be avoided or reduced more effectively on an isolated island, with a finite time period of bait
23 availability, than for rodent control operations on mainland or larger-island sites where
24 rodenticide is available in the environment chronically. Furthermore, the generally high cost and
25 logistical complexity of conducting a whole-island rodent eradication necessitate techniques and
26 tools that maximize the probability of successful eradication on the first attempt.

2.3.3 Bait Design and Application Requirements

35 The same bait would be used in all action alternatives, and it would be subject to a number of
36 limitations. The grain base of the bait pellets would be between 1 to 2 grams, containing 25ppm
37 brodifacoum. The bait would be a compressed grain pellet, approximately 1.1 g in weight,
38 containing 25 parts per million (ppm) brodifacoum, which is a second-generation anticoagulant
39 (see Section 2.5.2) for more information on brodifacoum). The bait used would be registered
40 with the EPA and in compliance with the Federal Insecticide, Fungicide and Rodenticide Act
41 (FIFRA). The bait product would be designed to be highly attractive to mice. All other
42 ingredients in bait pellets would be non-germinating grains (either sterile or crushed). Any bait
43 not initially consumed would likely remain attractive to mice for several weeks, although the bait
44 would likely disintegrate completely within one or two major rainfall events.

45 The pellet would be attractive as a food item only to granivorous and opportunistic omnivorous
46 animals. Insectivores such as some land birds, most shorebirds, and arboreal salamanders would

Comment [DG10]: Add Citation, support

2. Alternatives

1 not intentionally consume bait as food. Additionally, marine mammals and the majority of
2 seabird species that use the Farallones would not likely consume bait due to their piscivorous
3 diets. Pellets may be attractive to highly curious and omnivorous birds such as gulls, but this
4 would occur regardless of the inert “matrix” of the bait. Additionally, pellets would be dyed
5 green, which has been shown to make pellets less attractive to some birds, including western
6 gulls (Pank 1976b, H. Gellerman unpubl. data, Tershy et al. 1992b, Tershy and Breese 1994b).
7 The same pellets would be used in all aerial broadcast, bait station and hand baiting operations.
8

10 2.3.4 Aerial Broadcast Equipment

11
12 All three action alternatives would utilize some level of aerial bait broadcast and would be
13 conducted using a single primary-rotor/single tail-rotor helicopter. Helicopter models considered
14 for use in the operations would include the Bell 206B Jet Ranger, Bell 206L4 Long Ranger,
15 MD500, or other small- to medium-sized aircraft.
16

17 Bait would be applied from a specialized bait bucket, known as a hopper, slung beneath the
18 helicopter. The hopper would be
19 composed of a bait storage
20 compartment, a remotely-triggered
21 adjustable gate to regulate bait
22 flow out of the storage
23 compartment, and a motor-driven
24 broadcast device that can be turned
25 on (to broadcast bait over a wide
26 swath) and off (to trickle bait at a
27 low rate on a precise point below)
28 remotely and independently of the
29 outflow gate. The broadcast device
30 would include a deflector and a
31 skirt that can be easily installed
32 when directional (120° rather than
33 360°) broadcast is necessary, such as
34 on the coastline, so as to reduce the possibility of pellets reaching the ocean environment.
35

Figure 2.1 Bait hopper.

37 2.3.5 Aerial Bait Application Operations

38
39 The extent and timing of aerial broadcast operations is unique to each action alternative being
40 considered, but many aspects of the aerial operations are identical for all three. For aerial
41 broadcasts, helicopter operations would be staged on Southeast Farallon Island. Helicopters
42 would fly to designated staging areas on existing concrete pads where personnel would re-fill the
43 bait hopper, re-fuel the helicopter(s), and conduct other necessary maintenance. The staging area
44 would be adequately stocked with bait, fuel, personal protective equipment (PPE) and other
45 supplies and equipment to support the helicopters and project personnel during the bait
46 application process. The housing areas and lighthouse would be excluded from aerial broadcast

2. Alternatives

1 under all three alternatives and will instead be treated by hand-broadcast and placement of bait
2 stations.

3
4 Bait broadcast by helicopter would consist of low-altitude overflights of varying portions of the
5 land area of the South Farallones. The helicopter would fly at a speed ranging from 25-50 knots
6 (29-58 mph or 46-93 km/hr) at an average altitude of approximately 164 ft. (50 m) above the
7 ground, with the bait hopper long-lined 49-66 ft (15-20 m) below. The bait would be applied
8 according to a flight plan that would take into account:

Comment [DG11]: Confirm flight specs

- 10 • The need to apply bait evenly and to prevent any gaps in coverage or excessive overlap;
- 11 • Island topography to minimize any localized pooling of bait at the bottom of slopes;
- 12 • Distribution of roosting seabirds, especially gulls and Common murre (*Uria aalge*);
- 13 • The need to avoid bait broadcast into the marine environment;
- 14 • The need to minimize disturbance any pinnipeds hauled out on land;
- 15 • The need to avoid bait broadcast into residential areas and water catchment pads;
- 16 • Weather conditions; and
- 17 • The need to minimize the substantial costs associated with helicopter flight time.

18
19 The baiting regime would follow common practice based on successful island rodent
20 eradication elsewhere in the U.S. and globally (Howald et al. 2007a), in which overlapping
21 flight swaths are flown across the interior island area and overlapping swaths with a deflector
22 attached to the hopper (to prevent bait spread into the marine environment) flown around the
23 coastal perimeter. The width of a flight swath would be determined beforehand in calibration
24 trials. It would likely range from 30m to 80m. Each flight swath would overlap the previous by
25 approximately 25-50 percent to ensure no gaps in bait coverage. During one application all
26 points on the South Farallones would likely be subject to two helicopter passes. Within each bait
27 application, there would likely be no more than three consecutive operating days.

28
29 In order to ensure eradication success, it may be necessary to conduct more than one aerial
30 application. Two applications are standard procedure in mouse eradication using brodifacoum,
31 with applications usually between 5 and 21 days apart, to minimize the likelihood of either
32 competitively inferior adult mice or juvenile weanlings surviving the initial broadcast because
33 they were not given an opportunity to feed on bait. Nevertheless, if project leaders determine that
34 palatable bait would be likely to remain available for mouse consumption for longer than 10 days
35 after an initial application, a second or third application may not be necessary. Bait pellets
36 exposed to heavy moisture would degrade faster than pellets that fall in more protected locations.

Comment [DG12]: Add Citation

Comment [DG13]: Confirm application window, Citations, with weather contingencies

Comment [DG14]: Confirm date ranges and defensible thresholds for timing and bait rate for additional applications (second and third).

37
38 Bait would be applied strictly according to the limitations set by the EPA's pesticide regulations
39 (FIFRA). The precise bait application rate after all applications would be up to but not in excess
40 of 27kg/ha, the rate set by the EPA. The application rate is calculated so that an adequate amount
41 of bait is available for consumption by mice for a period of at least four days.

Comment [DG15]: Add language reflecting how "nominal" rate is calculated for EPA label

Comment [DG16]: Add citation for 4 days

42
43 Before bait application, the pilot, helicopter, and hopper combination to be used in the
44 application would conduct calibration operations to ensure consistency and accuracy of
45 application using a placebo bait broadcast. The calibration would occur over a test site off-island
46 in atmospheric conditions similar to those on the South Farallones.

Comment [DG17]: Need to add discussion as to whether stratified baiting rates are appropriate or not, based on current info

2. Alternatives

To ensure complete and uniform application:

Figure 2.3 Helicopter broadcasting bait.

- The actual application path would be monitored onboard the helicopter using an onboard global positioning system (GPS), a navigation bar, and a computer to precisely guide the application in order to avoid gaps and unanticipated overlaps in application. GIS grid lines would be mapped prior to broadcast and followed by the helicopter.
- The application rate would be calculated using the known rate of bait flow from the hopper, the helicopter's reported velocity, and overlaps in the bait swath reported by the helicopter's onboard GPS tracking system.

Adjustments in bait flow rates, helicopter speed, and flight lines would be made as necessary to meet the optimal application rate, staying within the limits legally required by the EPA.

As a result of the need for caution near the marine environment, the coastlines of the main islands and offshore islets, which are potential mouse habitat, may not receive the optimal bait coverage with helicopter broadcast alone. In cases where it is evident or suspected that any land area did not receive full coverage, there would be supplemental systematic broadcast either by foot, boat, helicopter, or any combination of the above. Helicopters may hover for brief periods over land during bait application to bait offshore islets, either by hand or from the hopper with the broadcast motor off to trickle bait at a precise point directly underneath. All personnel who may participate in supplemental hand broadcasts would be trained and tested in systematic bait application at a target application rate (Buckelew et al. 2005a). In coastal areas with irregular shorelines, aerial broadcast may be replaced by hand baiting to minimize broadcast of pellets into the marine environment, and to minimize any pockets of coastal habitat that could otherwise be subject to bait densities over the targeted application rate.

All personnel that handle bait or monitor bait application in the field would meet or exceed all requirements for personal protective equipment (PPE) required by the EPA. All bait application activities (aerial broadcast, hand broadcast, and bait station filling) would be conducted by or under the supervision of pesticide applicators licensed by the State of California.

Comment [DG18]: Add how these areas will be determined, and how additional rates will be calculated, as well as who will make the preliminary and final decision to apply more.

Comment [DG19]: Add additional description of how coastal circumference zone will be baited so as to avoid unintended overlap with parallel flight path baiting.

Comment [DG20]: Add other ways to do this based on recent success in the Galapagos

2. Alternatives

2.3.6 Bait Stations

All action alternatives would involve the use of bait stations as a delivery method to some extent. Bait stations are box-like enclosures with small entryways designed to be attractive to rodents, but difficult to navigate for other species such as birds (Figure 2.4). Bait stations reduce the risk of rodenticide exposure in non-target species by making bait more difficult to access and reducing the total amount of bait introduced into the ecosystem. The bait station design would effectively exclude birds while allowing easy access for mice. Bait stations would be deployed mostly on foot, but some might require rope, helicopter or boat transport in order to reach some areas.

Bait stations would be installed in and immediately surrounding all of the buildings and enclosed structures on the island in all three action alternatives. The bait used in bait stations would be identical to the bait pellets used for broadcast.

The bait station design for the Farallones would need to include the following characteristics:

- An entryway small enough to make entry by landbirds or cavity-nesting seabirds difficult, but large enough to allow for easy passage by mice
- An interior bait placement scheme that makes it very difficult for gulls or other curious larger birds to access the bait inside, as well as provide minimal difficulty for mice. This can be accomplished by placing the bait behind a baffle near the entryway that would block a gull's bill or foot.
- A "lockable" access panel that resists tampering by gulls but is easy to open by project personnel for station re-filling and maintenance.

2. Alternatives

1 A number of commercially-available bait stations fit these criteria and would be assessed for the
2 best choice prior to implementation. Alternatively, bait stations could be fabricated specifically
3 for this project.

Figure 2.4 Example of a bait station. Note: The design of bait stations used for this project may differ considerably from this picture.

4
5 Since bait stations would need to be accessed frequently during bait dispersal, the Service would
6 have to ensure that there is sufficient access ~~would have to be ensured~~ to each bait station. In
7 some cases no landscape modifications would be necessary; however, depending on the local
8 placement of each station, a number of landscape modifications and/or installations may be
9 necessary to properly secure bait stations into place. Examples of these modifications could
10 include:

- 11 • Paths cut through vegetation for stability;
- 12 • Installation of boardwalks to avoid trampling seabird burrows or other sensitive
13 resources;
- 14 • Anchor points, ladders, and fixed lines to allow for safe access to bait stations placed on
15 steep and/or unstable terrain.
- 16 • Some bait stations may also require modification (i.e. additional covering) to prevent rain
17 or moisture from entering the box and damaging the bait.

18
19 Some access pathways may need to be crossed especially in sensitive habitat such as areas with
20 seabird nest burrows and rocky talus slopes that harbor seabird nest crevice habitat. Whenever
21 possible, access paths would be routed around sensitive biological habitat, or temporary
22 platforms, walkways, or other temporary infrastructures would be installed to avoid trampling.
23

24 Each bait station would be secured to the ground with anchors placed into the soil or drilled into
25 the rock as appropriate. The infrastructure required for the bait station grid would be durable
26 enough to withstand the corrosive marine environment of the Farallones for up to two years, but
27 it would be removable and not a permanent fixture on the islands.
28

2. Alternatives

1 The use, placement and number of bait stations to be used would be unique to each alternative
2 considered, but they would be used to treat buildings in all three alternatives, as discussed below.

3 4 **2.3.7 Treatment of Buildings**

5
6 The buildings on the Southeast Farallon Island, especially residences, provide high-quality
7 habitat for mice, in that they provide food sources as well as shelter from the elements. Because
8 two of the structures on island are residences, they would be excluded from any aerial bait
9 application and the area within and around them would instead be baited with enclosed bait
10 stations. The power house, outbuildings and concrete water catchment basin would also likely
11 be within the aerial broadcast exclusion zone. The perimeter of these buildings and structures
12 would be hand-baited and baited with enclosed bait stations. The water catchment area might be
13 tarped to avoid the drift of any bait into this area, and bait applied by hand and/or bait stations
14 surrounding this area to avoid the entry of brodifacoum into the water collection system.

15
16 Ensuring that mice are removed completely from all buildings would be critical to the success of
17 the proposed action. A preliminary rodent exclusion needs assessment of the houses and other
18 man-made structures on Southeast Farallon was conducted in October 2010 (Badzik, B. 2010).
19 This assessment was conducted by the Integrated Pest Management Coordinator of the National
20 Park Service that conducted and oversaw a similar successful rodent eradication effort on
21 Anacapa Island in the Channel Islands National Park in 2001. This report identifies the
22 preliminary actions that must be employed by the USFWS and PRBO prior to the eradication in
23 order to ensure that no residual mice will be left within these structures afterwards to serve a
24 recolonizing population (Appendix XX).

25
26 The Service and PRBO have already begun taking measures to begin sealing off access by mice
27 to the interiors of the two residences. Additional work must be conducted to eliminate access by
28 mice to any external or other portions of the houses, such as foundations, crawl spaces, attics
29 and within the walls and pipes. Sealing other access points and holes to interior spaces will also
30 need to be continued for the power house and other buildings on the island.

31
32 Sources of food for mice in and around residences will also need to be eliminated in the months
33 leading up to the eradication. The island's compost system, recycling system and treatment of
34 food storage and waste will need to be modified so as to avoid providing mice with access to any
35 items. Prior to the initiation of whole-island eradication, the Service and PRBO would take
36 further steps to "mouse-proof" residences and other island buildings, cisterns and pipes by
37 sealing possible entryways for mice, setting traps in and around buildings, and eliminating
38 mouse access to any food or food scraps. Throughout the course of the operation, personnel on-
39 island would be required to adhere to strict protocols to reduce the availability of food for mice
40 within residences. During the operation, a high concentration of bait stations would be installed
41 and maintained inside and outside all structures on the island.

42
43 During detailed operational planning, structures would be examined carefully in order to
44 determine if mice can likely be eradicated from buildings using bait stations alone. If a pest
45 control specialist determines that bait alone may not be sufficient to ensure complete removal of
46 mice from structures, it may be necessary to use a fumigant in one or more buildings. If the

Comment [DG21]: Create a list and timeline of tasks and operations to be conducted leading up to eradication.

2. Alternatives

1 Service determines that a fumigant would be necessary to ensure a successful eradication, a
2 building-treatment protocol would be developed and implemented.

Comment [DG22]: Would using a fumigant require additional Env. Compliance/Permits?

3
4
5 **2.3.8 Timing Considerations**

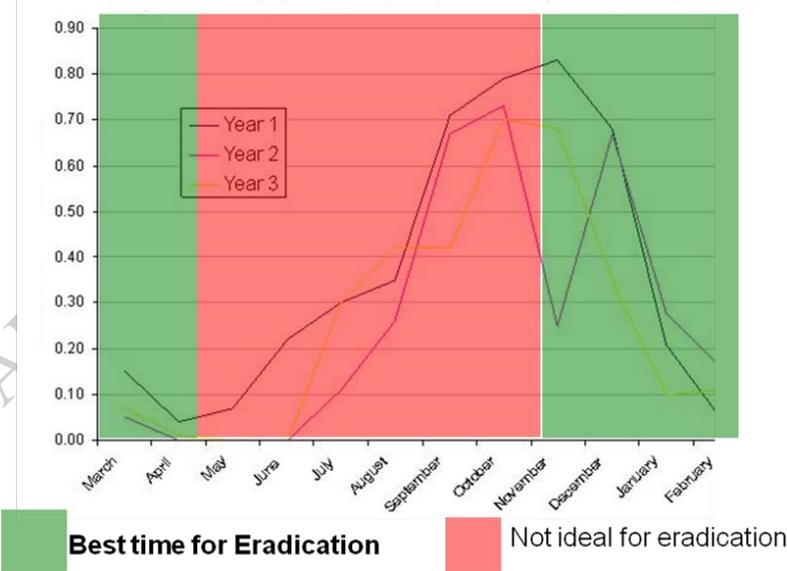

6
7 The seasonal timing for the action alternatives would be a critical factor for both the likelihood
8 of successfully eradicating mice and reducing the risk of negatively impacting the biological
9 resources of the South Farallones. The likelihood of success is influenced by three seasonally-
10 dependent factors: 1) the local population biology of mice; 2) the availability of alternative food
11 sources for mice; and 3) local weather conditions and seasonal patterns that would affect the
12 feasibility of conducting operations. The risk of negatively impacting the biological resources
13 depends on the local seasonal population biology of the vulnerable species, the breeding and
14 migratory patterns of non-target species that may be vulnerable to rodenticide exposure, and the
15 disturbance caused by the bait application process.

16
17 **2.3.8.1 Biology of mice**

18 Mouse eradication from an island is more likely to be successful if intensive baiting takes place
19 when the mouse population is declining in response to annual resource declines. At this time,
20 mice are typically more food stressed and therefore more likely to eat the bait presented. The
21 probability of success is also increased if bait application takes place when mice are not
22 breeding. During breeding seasons, there is a possibility that weanling mice could still be too

Timing

Farallon mouse population cycle (mouse trap success by month)

23
24

2. Alternatives

1 young to leave the nest at the time of bait application. These weanling mice could be mature
2 enough to emerge from the nest only after all the bait nearby has been consumed, and could
3 therefore re-populate the island.

4
5 Mice in reproductive condition have been trapped on the South Farallones year-round, indicating
6 that breeding may never completely cease; however, mouse trapping rates normally begin
7 declining in November and fall dramatically between December and April, indicating that the
8 number of mice on the island also declines (Irwin 2006). From the perspective of mouse
9 population ecology, the ideal time period for mouse eradication would be between the months of
10 November and April.

Comment [DG23]: We will revise this figure to include seabird breeding times, MM pupping, and rainfall and # of gulls

13 2.3.8.2 Seasonal sensitivity of native wildlife

14 The effects of the operational activities associated with mouse eradication (e.g., helicopter
15 operations, bait station installation and maintenance) on the native wildlife of the South
16 Farallones, particularly birds and marine mammals, would be reduced by avoiding seasons in
17 which large wildlife populations are present, such as breeding and migration. Bait station
18 maintenance would be required year-round, which would lead to wildlife disturbance in many
19 cases; therefore, the initial installation of bait stations would be timed to avoid peak wildlife
20 activity. Bait broadcast operations would occur during a season with minimal wildlife activity.

21 Specific timing considerations for birds include the following:

- 22 • Seabirds generally breed on the South Farallones between mid-March and October, with
23 the peak breeding season for most species lasting from late April to mid-August. The
24 relative abundance of many of the seabird species on the South Farallones declines after
25 the breeding season, which reduces the number of seabirds that could be exposed to
26 rodenticide— particularly for gulls – or disturbed by aerial application procedures.
- 27 • Migrant seabirds, landbirds, and shorebirds stop frequently on the South Farallones
28 during spring and fall. Between November and February, however, only a small number
29 of overwintering and visiting birds are present on the island – a daily average of around
30 30 landbirds and around 60 shorebirds between mid-November and mid-December
31 (PRBO unpubl. data).

32
33
34 Specific timing considerations for marine mammals include the following:

- 35 • The main pinniped breeding season on the South Farallones occurs between March and
36 September. This encompasses the breeding seasons for California sea lions (*Zalophus*
37 *californianus*), harbor seals (*Phoca vitulina richardsii*), northern fur seals (*Callorhinus*
38 *ursinus*), and Steller sea lions.
- 39 • Northern elephant seal pups are born on the South Farallones between late December and
40 late February. Pups are weaned at about four weeks old, and pups remain onshore in
41 groups for up to 12 weeks, before departing for the sea. All pups should have dispersed
42 from the island by the end of June (Le Boeuf and Laws 1994).
- 43 • Both harbor seals and northern elephant seals undergo an annual molt using the South
44 Farallon Islands as a haulout site. Molt occurs at the end of the breeding season for
45 harbor seals, from July to mid-September (Daniel et al. 2003). Northern elephant seals
46 molt according to a rough schedule stratified by gender and age class. Juveniles and

2. Alternatives

1 females molt starting in March, followed by sub-adult and then adult males, which molt
2 through July (Le Boeuf and Laws 1994). During molt, pinnipeds undergo a short period
3 of rapid hair loss during which time they may be reluctant to enter the water.
4

5 Disturbances to pinnipeds during critical activities such as breeding and molting can be
6 particularly harmful. Conducting major operations such as aerial bait broadcast or bait station
7 installation outside of these sensitive periods would substantially reduce the potential for harm to
8 pinnipeds on the South Farallones.
9

10 From the perspective of minimizing risks to native wildlife, the acceptable time period for the
11 majority of the eradication operations would be between October, when the seabird breeding
12 season has largely concluded, and the end of December, before the first northern elephant seal
13 pups are born. The ideal time, particularly for aerial broadcast, would be from November to mid-
14 December.

2.3.8.3 Weather considerations

15
16 While the climate of the Farallones does not fluctuate dramatically by season, the months of
17 November through March are noticeably more unsettled and stormy (Null 1995). Weather
18 conditions must be fairly calm to effectively broadcast bait by helicopter, with average wind
19 speeds lower than 30 knots (35 mph). It is important to the success of the eradication that areas
20 that are treated by bait broadcast be conducted within a time frame that is as short as possible,
21 rather than in partial-island stages separated by multiple days or weeks. This consideration would
22 prevent the potential reinvasion of mice back into areas previously treated with bait.
23 Furthermore, the dry bait formulation used would not long withstand substantial rainfall events,
24 so it would be important that the bait application is implemented on a day with no precipitation
25 in the near-term forecast. The likelihood of getting a long enough period of ~~calm~~ weather
26 to complete a full bait application is more uncertain during the late fall and winter than during other
27 seasons. However, the biological considerations of both sensitive native species and mice
28 indicate that the late fall is the only reasonable effective time to conduct a bait application. While
29 the late fall is not ideal from the perspective of helicopter operations and bait integrity, it is
30 nevertheless likely that there would be ample opportunity to conduct two complete aerial
31 broadcasts during the time period of November through December.
32
33
34

2.3.9 Preventing Bait Drift into the Marine Environment

35
36 Every reasonable effort would be made to minimize the risk of bait drift into the marine
37 ecosystem. The broadcast deflector would be attached to the hopper for all treatment passes of
38 coastal bluffs and cliffs. The deflector would broadcast bait within approximately 120° of the
39 onshore side of the helicopter, to minimize the risk of bait entering the ocean on the opposite, or
40 seaward, side. Additional measures to reduce bait drift into the marine environment include
41 reducing the aerial swath application width from 60m to 30m, which would allow for more
42 precise placement of bait
43
44

45 Additionally, the hopper may be used with the broadcast motor off to trickle bait in precise
46 points directly underneath, along the coastal perimeter of the island. Many areas along the shore
47 and near intertidal zones that present the greatest risk of bait drift will be baited by hand from

Comment [DG24]: We will create a graphic showing the timing of the major variables (breeding seabird timing, gull#s, marine mammal breeding, mice#s, rain, and a more expanded rationale for this window of time.

Comment [g25]: We will add weather data for at least 10 years if available. Email Tom from NOAA?. Temp and Precipitation.

Comment [g26]: We will discuss the CWA NPDES permitting once we know better how it will be dealt with!

2. Alternatives

1 land or possibly by hand from a boat or helicopter to ensure that as little bait as possible drifts
2 into the marine environment.

Comment [DG27]: Reiterate other methods to reduce bait drift, mentioned earlier

2.3.10 Reducing Wildlife Disturbance

6 Before eradication operations begin, personnel would be briefed on strategies and techniques for
7 avoiding wildlife disturbance whenever possible, and these techniques would be implemented
8 during actual eradication operations. The requirements to reduce wildlife disturbance would
9 include:

- 10 • Crouching or crawling when necessary to remain out of view of nearby animals,
11 especially during the breeding season
- 12 • Moving slowly and deliberately to avoid frightening animals
- 13 • Traveling carefully by foot and avoiding sensitive areas when possible to reduce potential
14 disturbance to seabird nest sites and marine mammal haul-out sites
- 15 • All staff would be shown maps detailing areas with sensitive wildlife and trained on how
16 to avoid disturbing wildlife and avoiding impacts to sensitive habitats such as nesting
17 burrows and crevices. These sensitive wildlife areas are fully described in Section 3.

2.3.11 Protecting Cultural Resources

22 Project personnel would exercise caution in general in order to not disturb the cultural or
23 historical resources that have been identified on the South Farallones. Additionally, planning for
24 the final layout of the bait station grid would be conducted in consultation with the State
25 Historical Preservation Office so as to avoid inadvertently damaging buried resources during bait
26 station installation. Personnel would be briefed on the known locations and identification of
27 archaeological and historical resources that may be present on the islands. All known sites of
28 significance would be clearly marked with weather-resistant marking materials that are
29 recognizable to all field personnel. Field personnel would be prohibited from disturbing any sites
30 of historical or cultural importance. Due to the presence of historic buildings and other features
31 on the island, the Service would consult with an archeologist from the State Historic Preservation
32 Office (SHPO) to ensure that planned activities would be compatible with protection of cultural
33 resources on the island.

2.3.12 Minimizing Impacts to Wilderness

37 To address the special management regulations for the wilderness area on West End Island of the
38 South Farallones, the Service would:

- 39 4. Avoid touching down in a helicopter anywhere other than the established helicopter
40 landing zone on Southeast Farallon Island except in an emergency.
- 41 5. Minimize travel to West End and only for activities necessary for the eradication, such as
42 bait delivery, bait station installation and maintenance, non-target mitigation actions
43 including monitoring pinniped responses to helicopter operations, and efficacy
44 monitoring such as setting traps.

Comment [DG28]: Can we be dropped off on West End to hand bait areas and to do mitigation/monitoring?

2. Alternatives

- 1 6. Choose aerial broadcast before bait station installation in wilderness areas where bait
2 station installation would require greater-than-normal habitat modification such as
3 frequent visits on foot, extra anchors or breaking rocks.
4

5 2.3.13 Minimizing Impacts to Birds

6
7 Some non-target bird species may be exposed to the bait either directly by consuming the bait
8 pellets or indirectly by consuming mice or other organisms that have eaten the bait. A percentage
9 of the resident raptors and gulls on the island at the time of the application may experience
10 exposure to the bait without some form of specific efforts to avoid such exposure. Mortality
11 reduction methods to be employed for all action alternatives would include:

- 12 • Systematic attempt to remove mouse carcasses, bird carcasses or that of any other animal
13 found that is suspected of having succumbed to the toxicant, to reduce the likelihood of
14 secondary exposure in scavengers;
- 15 • Attempting to capture and relocate all transient burrowing owls arriving on island to the
16 mainland, as the Service has done in the past, to reduce the risk of toxicant exposure; and
- 17 • Efforts to capture, hold and release other resident and migrating raptors present, including
18 the resident pair of Peregrine falcons and Common ravens (*Corvus corax*), until the
19 Service determines the birds would no longer be at risk of exposure to toxicant;
- 20 • Attempt to reduce gull pellet consumption and non-target mortality by utilizing gull
21 hazing techniques developed and tested during a January 2011 hazing trial.
- 22 • Installing bait stations rather than broadcasting bait in areas that are determined to have
23 particularly high concentrations of birds that would be likely to feed on bait pellets after
24 an aerial broadcast.

Comment [DG29]: Describe level of effort to be applied for this, areas, and timing of search

Comment [DG30]: Discuss if will capture/release other bird species (e.g. granivorous passerines migrating through) during the application?

Comment [DG31]: Are these areas just around the houses? Gull roost areas too?

25 26 27 2.3.14 Monitoring Eradication Efficacy and Ecosystem Response

28
29 Please refer to the Eradication Monitoring Plan presented in Appendix XX for a more detailed
30 description of the monitoring activities that would surround the mouse eradication. The species
31 and systems that would receive the most intensive monitoring are described below.
32

33 2.3.14.1 Mouse monitoring

34 During and after bait application activities, the mouse population on the South Farallones would
35 be monitored for 2 years from the onset of the eradication operation to assess the effectiveness of
36 eradication efforts.
37

38 For the action alternatives that employ aerial bait-broadcast as the primary rodenticide delivery
39 method, rodent detection devices such as traps, flavored chew blocks, tracking tunnels, and
40 motion-sensing cameras would be deployed in a post bait application efficacy monitoring
41 program that would attempt to detect remnant mice where additional treatments or “mop up”
42 response baiting is feasible. Also, radio collars would be deployed on a sample number of mice
43 captured on Southeast Farallon Island prior to the bait application. The collared mice would be
44 monitored just prior to the bait application, and then after bait application to confirm mortality,
45 as well as time and location of mortality.
46

2. Alternatives

1 For the action alternatives that employ bait-stations as the primary rodenticide delivery method,
2 eradication efficacy would be measured by the recording of station activity and by chew blocks
3 and tracking tunnels associated with the stations. Passive observation by PRBO, and USFWS
4 field station staff and visiting scientists would also be a very effective post-eradication efficacy
5 monitoring measure. Due to the seasonal abundance of natural food resources and mice on the
6 Farallones, a remnant mouse population should become readily detectable within one year of the
7 eradication effort. Live or snap-traps set in and around the houses and buildings will be set and
8 checked regularly.

Comment [DG32]: Decide whether to include the possibility of using trained dogs in visits to detect mice after eradication

9
10 For aerial broadcast alternatives, a team would return to the South Farallones four to six weeks
11 after the second bait application to establish mouse detection stations throughout the islands.
12 The detection station network would consist of corrugated plastic indicator blocks, tracking
13 tunnels and/or a motion sensing camera traps. The stations would be checked and serviced every
14 three days over a fifteen day period. If mice sign is detected on an isolated area that is small
15 enough to effectively retreat by hand, the monitoring team would consult with the project
16 management team about conducting a follow-up bait application on this area.

Comment [DG33]: Confirm timing specs

17
18 Detection stations that are placed on the islands would be monitored and serviced by trained
19 PRBO and USFWS station staff according to this schedule: once per week for six months
20 following the eradication, once per month after six months. At one year and two years after the
21 eradication, a monitoring team would return to re-establish the mouse detection stations. During
22 these monitoring efforts, live traps would be added to the detection station network, and stations
23 would be monitored and serviced every three days.

Comment [DG34]: Confirm timing specs

2.3.14.2 Pinniped Monitoring

24
25
26 Pinniped including northern elephant seals *Mirounga angustirostris*, California sea lions
27 *Zalophus californianus*, harbor seals *Phoca vitulina richardsii*, northern fur seals *Callorhinus*
28 *ursinus*, and Steller sea lions *Eumetopias jubatus* will be monitored the Service and its
29 contractor to see the response of pinnipeds to all activities, including helicopter operations, bait
30 station installation and maintenance, and other project tasks to ensure compliance with the
31 Marine Mammal Protection Act (MMPA) and the ESA. This observational monitoring is
32 discussed in detail in Appendix J. Prior to conducting any aerial broadcasting or bait station
33 installations, a visual survey of the island will be conducted by PRBO or USFWS personnel to
34 determine the location and numbers of marine mammal haul-out sites, in order to determine what
35 type of measures need to be employed to avoid unnecessary disturbances to the species present.

Comment [DG35]: Mention here the use of MM biologist in aerial survey/approach prior to baiting or other activities that could disturb pinnipeds..

2.3.14.3 Bird, Reptile, Plant Monitoring

36
37
38 Biological monitoring on the South Farallon Islands, conducted primarily by PRBO
39 Conservation Science in cooperation with the Service, has been an integral part of the
40 management of the islands for over 40 years. The monitoring activities currently include a wide
41 array of monitoring that includes ongoing weekly and daily studies and counts of marine
42 mammals, birds, plants and arboreal salamanders. The Refuge's current monitoring activities fall
43 outside the scope of this specific action, and would continue independent of the results of mouse
44 eradication, so their environmental impacts are not analyzed here; however, they will be
45 considered in the cumulative impacts analysis, in Chapter 4. The ongoing monitoring programs
46

2. Alternatives

1 would provide valuable information on the ecosystem's response after mouse eradication, using
2 baseline data from before the mouse eradication for comparison in order to detect any positive or
3 negative changes. ~~Ongoing acoustic monitoring studies as well as~~ breeding bird counts would
4 monitor the effect of the mouse eradication effort on affected seabird species.

Comment [DG36]: True? Or will additional breeding/non-breeding counts be needed?

6 Monitoring of abundance and distribution of native and invasive plant species would be
7 conducted annually by the USFWS and PRBO as part of their ongoing habitat assessments and
8 non-native plant control efforts.

Comment [DG37]: Would any additional vegetation mapping of natives and invasives like NZ spinach, be necessary/helpful?

10 The additional monitoring activities that would be necessary to determine the success of the
11 eradication would largely be incorporated into ongoing monitoring activities for other aspects of
12 the ecosystem, without adding more than a negligible amount of additional environmental
13 disturbance. The current ongoing monitoring activities fall outside the scope of analysis of this
14 document, and thus post-eradication monitoring activities will not be analyzed in detail here.

16 The timing of the eradication prior to the arrival, or after the departure of most nesting seabirds
17 would be the most effective strategy to minimize the risk of short term rodenticide exposure in a
18 bait broadcast scenario. The Service and its partners would continue to actively monitor the
19 resident bird populations and continue their searches for dead or moribund individuals,
20 especially gulls during and directly after the bait application period. The long term risk of
21 rodenticide exposure to non-target shorebirds is low given the low rates of toxicant migration
22 into the soil and the quick decline in toxicant residues, however, regular and opportunistic
23 monitoring of the shorebird and seabird populations would continue as part of the Service's
24 ongoing resource management plan for the Refuge.

26 Three additional monitoring activities would be conducted specifically to assess the effects of the
27 eradication:

Comment [DG38]: Need to elaborate on existing databases/studies as well as monitoring studies that may need to be initiated prior to a broadcast (gulls, raptors, cricket surveys) and continued for 2 years afterwards.

2.3.14.4 *Invertebrate and Intertidal Monitoring*

- 31 • Monitoring of the near-shore fish and intertidal invertebrates in the marine environment
32 would be coordinated and conducted by ~~Dr.~~ Jan Roletto, Research Coordinator for the
33 Gulf of the Farallones National Marine Sanctuary (GFNMS). Pre-existing monitoring
34 plots that have been monitored annually by NOAA for decades would be visited in the
35 weeks following the bait applications in order to determine if the fate and concentrations
36 of any rodenticide that may find its way into the intertidal marine environment during the
37 operation. Similar studies have been conducted during and after other rodent eradications
38 on the Channel Islands National Park off southern California in (Howald et al. 2001)-
39
- 40 • Monitoring of bait drift into the marine environment from aerial application would be
41 conducted by placement of tarps over sample areas of inter-island channels, (such as
42 Jordan Channel) so that the number of bait pellets (if any) landing on the tarp can be
43 immediately counted and an island-wide marine bait drift amount can be calculated.

Comment [DG39]: Add citation to references: 2001. Progress in Rat Eradication, Anacapa Island, Channel Islands National Park, California Gregg R. Howald, Bernie R. Tershy, Bradford S. Keitt, Holly Gellerman and Donald A. Croll

Comment [DG40]: This is a suggestion based on the Palmyra EIS plans using this technique.

2. Alternatives

- Surveys for endemic cave-dwelling camel crickets (*Farallonophilus cavernicola*) would be conducted before and one year after eradication, as standardized surveys for this rare endemic have not been conducted recently. It is expected that the eradication of predatory mice would generally result in increases in the numbers of invertebrates (as well as salamanders, native plants and some seabirds on the island, including the Ashy storm petrel and Cassin's auklet).

2.3.15 Public Information

All of the Farallon Islands are off-limits to the general public, and access can only be granted by permit issued by the USFWS. The waters surrounding the islands are productive fishing grounds, but most adjacent waters are within the recently-established Southeast Farallon Island Marine Reserve). Waters outside of the Reserve do provide recreational opportunities for fisherman, and whale watching boats from the nearby San Francisco Bay Area do visit the waters within the reserve. Informational posters describing the eradication actions taking place on the South Farallones would be distributed to tour boats that visit the islands as appropriate to ensure public safety and as an opportunity for interpretation, as well as, posted at nearby ports from which ships might embark for the vicinity of the islands.

Comment [g41]: Add Marine Reserve Map
Update the status of the Marine Reserve.

Researchers that are permitted to conduct research on or near the island would be informed directly about eradication activities and timing, and all research activities would be adjusted to accommodate the eradication project. All approved island users such as research biologists, technicians, contractors, and volunteers would be given written materials stating that brodifacoum is present on the island, describing its appearance, and its intended purpose. In addition, approved pesticide warning and informational signs would be posted in the island's research housing and at all reasonable access points to the island. All island visitors would receive these materials, and signs would remain visible, until bait pellets are no longer found, which is estimated to be no more than three months after bait application has been completed, but subject to actual uptake rates and weather conditions.

2.3.16 Rodent Introduction Prevention and Response to Rodent Detection

The benefits of a successful eradication could be lost with the introduction of even one pregnant female rodent. Rodents can be accidentally transported to islands and escape from:

- Cargo such as food boxes, personal gear, construction, or other bulk materials
- Watercraft moored directly to the island or anchored nearby
- Debris washed ashore from the mainland
- Sinking or disabled vessels
- Aircraft that land on the island

2. Alternatives

2.3.16.1 Re-introduction Prevention

The Service currently requires personnel, partners, and contractors traveling to the island to abide by a rodent and invasive plant exclusionary plan, but the requirements of this plan are not always enforced. These requirements include the following measures:

- Insuring through physical inspection that all materials and equipment transported to the island are free of seeds, plant materials, or rodents
- Managing any mainland staging/storage areas so as not to attract rodents
- Using only new materials for construction projects
- Transporting materials in rodent proof containers
- Implementing these measures would be thoroughly reviewed and enforced beginning before mouse eradication is complete. Full compliance among all island visitors would be essential.

To mitigate for post eradication rodent reinvasion risk, these biosecurity measures will need to be implemented and enforced more regularly and strictly. In addition, a combination of available rodent traps and bait stations would be maintained at the East and North Landing areas, the helicopter landing pad, and at any additional landing areas that may be utilized in the future.

A Farallon National Wildlife Refuge Biosecurity Plan would be written that includes specific rodent re-introduction prevention and response measures to be employed.

Comment [DG42]: Let's discuss this aspect.

2.3.16.2 Response

After the Service has determined that the eradication operation has concluded, personnel remaining on the island would continue to monitor the island for new rodent introductions or the possibility that some mice remained after eradication operations. In the event that rodents are detected after eradication operations have ended, a rodent response plan would be implemented immediately. The response plan would include, at minimum, the installation of bait stations in an area immediately surrounding the site of a rodent sighting. If necessary, bait would also be hand- or aerially broadcast within the seasonal constraints described in Section 2.3.6.

Comment [DG43]: Develop application rates more fully in subsequent versions

2.4 Preliminary Bait Trial Results

As part of the development of potentially successful action alternatives, a field trial using non-toxic bait pellets was conducted in the fall of 2010 in order to better inform the efficacy and potential risks associated alternative operational plans that are being developed. A full account of the Biomarker Trial Plan (Grout, D. 2010) results can be found in the Farallon Biomarker Trial Report (Appendix #XX).

Comment [DG44]: Final analysis and report not yet completed.

2.4.1 Bait Trial Introduction

During November 2010, the Service conducted a non-toxic bait application trial on the South Farallones as part of the development and testing of operational alternatives. A placebo cereal bait without any rodenticide but instead infused with a non-toxic biomarker was hand broadcast in a study area on Southeast Farallon island. The non-toxic bait had a green food-quality dye that fluoresces under Ultraviolet (UV) light so that it could be detected in mice and throughout the

2. Alternatives

1 greater environment. Bait was applied by hand in a portion of the island accessible on foot and
2 in a manner that did not have any potential for impacts to natural resources on the island.

3 The two main goals of the biomarker trials were to:

- 4 • Assess the palatability and efficacy of mouse eradication attempts utilizing the
5 bait pellet at the registered EPA label application rate; and,
6
7
- 8 • To evaluate the potential risks to non-target species exposure to the bait,
9 especially in gulls but also in other taxa, in order to assist the Service in
10 developing measures to avoid, reduce and/or minimize these impacts.

11 Additional studies were also conducted during the trial to determine the following:

- 12 • Assess mouse abundance and current phase of the population cycle
- 13 • Determine if mice are still breeding at this time of year
- 14 • Bait pellet acceptability and preference by mice
- 15 • Biomarker detectability and persistence time in mice
- 16 • Bait pellet degradation and weathering rates
- 17 • Estimate rates of bait removal by mice and gulls
- 18 • Collect 50 DNA samples from mice on both Southeast Farallon and West End
- 19 • Locate and assess caves, coves and areas that may need special treatment
- 20 • Delineate which areas can/should be treated using bait stations
- 21 • Assess treatments that may be needed for buildings or other man-made features
- 22 • Determine access to various portions of the islands and surrounding islets
- 23 • Estimating the number of gulls and other non-target bird species on the islands

24 A full account of the study area, methods and results of the 2010 biomarker trial can be found in
25 Appendix #XX?, but are summarized in the following Sections 2.4.2 through Section 2.4.4.

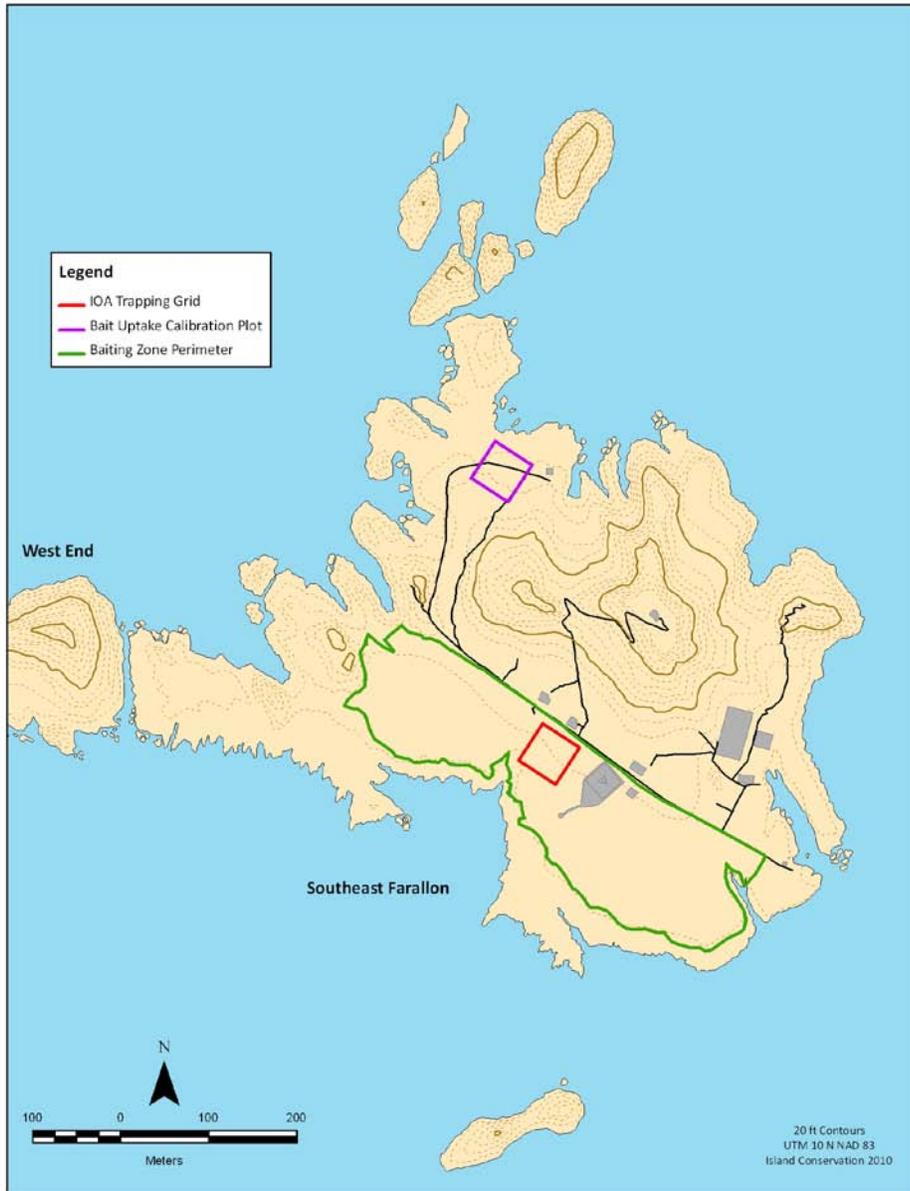

2.4.2 Study Area

26 The biomarker trials were conducted on Southeast Farallon Island, primarily on the marine
27 terrace area on the southern portion of the island. Figure ## shows the primary bait trial study
28 areas used in the fall of 2010. A 50m x 50m bait broadcast study plot was selected in the North
29 Landing area to calibrate the expected bait uptake rates to be used during the subsequent field
30 trial. A 6.4ha bait zone was selected for the actual biomarker baiting trial. A 0.25ha plot within
31 this study area was chosen to determine an index of abundance for mice. To determine exposure
32 to the biomarker, mice were live-trapped in and around the large baited area on two core trapping
33 plots and along two trap transects to inspect mice for fluorescent marking indicative of bait
34 consumption.

35 Ten 50m x 1m bait uptake plots were established within the bait zone to determine daily uptake
36 rates of bait. Uptake transects 1-8 consisted of two transects placed on either side of the two core
37 trapping plots, and the other two transects were placed so as to assess bait uptake in the Index of
38

1 abundance plot (9) and within a known gull roost site (10). Additional studies were conducted in
2 other portions of Southeast Farallon, West End and surrounding islets (See Appendix #XX for a
3 full description.
4

6 **2.4.3 Methods**

8 *2.4.3.1 Index of Abundance*

9 A mark-recapture live-trap grid was set up to obtain an index of mouse abundance (Figure ##).
10 A total of 100 traps were set up in 10 by 10 grid pattern, with traps spaced 5m apart. Traps were
11 set each evening and checked each morning for five consecutive nights during favorable weather
12 conditions. The trap grid utilized Sherman live-traps baited with rolled oats. All captured mice
13 were weighed, and inspected for sex, age and reproductive condition. All mice were marked with
14 a unique Monel ear tag and released unharmed at the site of capture.
15

16 Additionally, a set of four transects trap lines comprised of 38 trap sites were established to be
17 trapped monthly for the next year to establish a monthly index of abundance of mice based on
18 capture success rates. These transects and methods were largely based on re-initiating the
19 previous index of abundance mouse trap lines used by the USFWS in 2002-2004, although five
20 additional trap locations were added to one of the transects in 2010 in order to better assess the
21 Lighthouse Hill area (Figure ##).
22

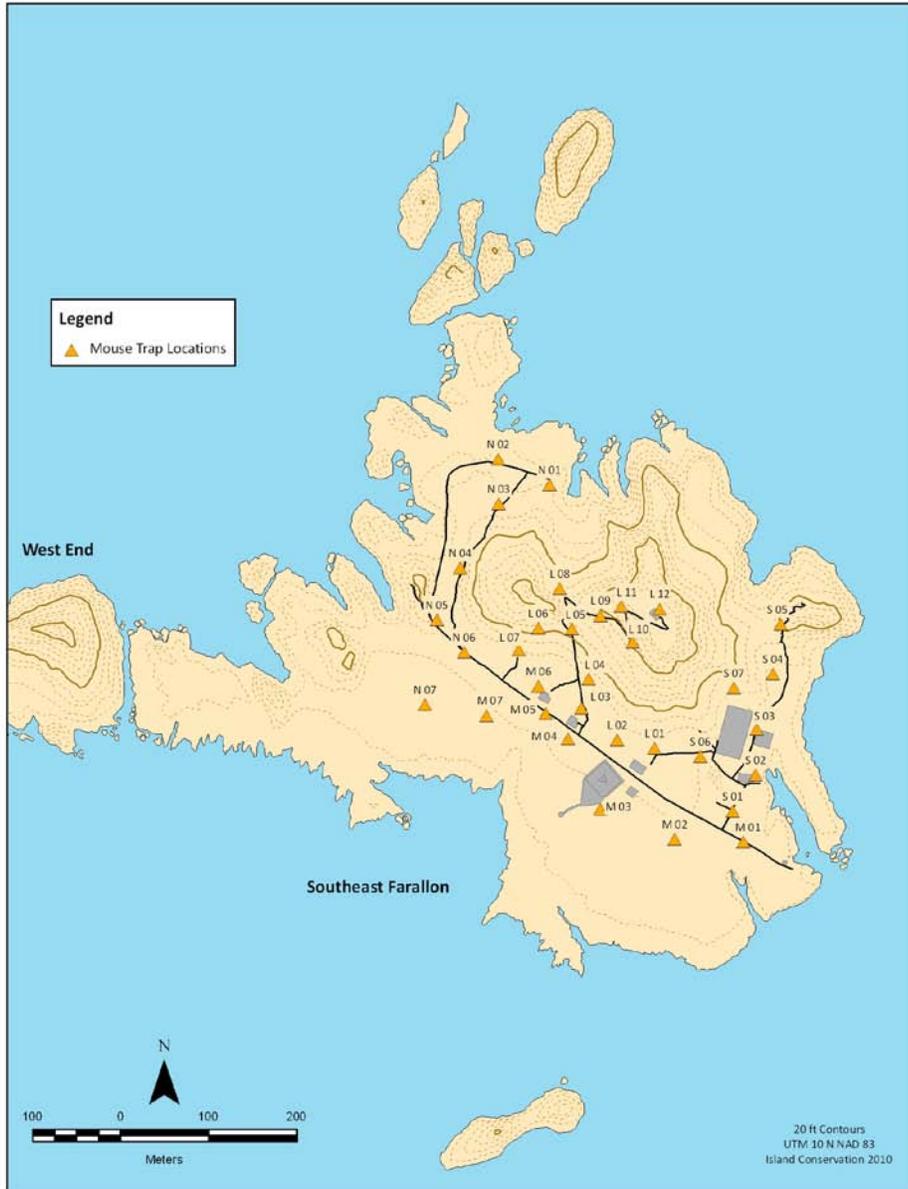

23 *2.4.3.2 Bait Application*

24 A small 50m x 50m calibration area at North Landing was initially baited at 27kg/ha to assess if
25 the EPA label bait application rate to be used during the subsequent bait trial would result in bait
26 remaining on the ground for enough days to be effective. While bait uptake during this
27 calibration was faster than expected, some of the increased uptake was likely due to edge effects
28 and non-target uptake by gulls roosting in this area. Results of this calibration experiment
29 informed the application rates and methods for the larger trial conducted in the following days.
30

31 In order to replicate a toxic bait operation as closely as possible, a large contiguous 6.4ha area of
32 the island was hand-baited with non-toxic bait pellets. Baiting was conducted from a pre-
33 determined baiting grid with bait broadcast locations spaced every 10 meters and located using
34 hand-held GPS units and marked with biodegradable spray paint. Bait pellets were hand cast by
35 four to eight people walking abreast along linear transect and distributed continuously over a 5m
36 radius in all four directions. This simulated an aerial drop of equivalent densities of toxic bait.
37 Baits were broadcast at 18kg/ha throughout the study area during the first application. A second
38 bait application occurred five days later. On the second application, bait was broadcast on
39 approximately western half of the study area (A) at 18kg/ha (west of the Helicopter pad), and on
40 the eastern half (B) at 9kg/ha. Therefore study area B received a total of 27kg/ha, which is the
41 registered bait application rate for the toxic form of the bait pellet, while study area B received
42 36kg/ha, which was tested to see if additional bait density might be needed to ensure that all
43 mice in the core of the bait zone would receive the equivalent of a lethal exposure of bait.

2. Alternatives

1

2 We used a standard toxin-free cereal bait of the type used in rodent eradications: Conservation
3 25D produced by Bell Labs in a 1.1g dry formulation, infused with pyranine.
4

2. Alternatives

1
2 Mice appear unable to detect brodifacoum at concentrations used in rodent eradications, making
3 the results of this trial directly comparable to toxic operation (O’Conner and Booth 2001).
4 Pyranine fluoresces strongly under ultraviolet (UV) light and be detected visually on the feet,
5 mouth, anus and alimentary tract of mice several days after consumption. Baits were applied
6 twice, five days apart. To ensure that all trapped mice were exposed to the bait, and were not
7 animals that had ranged into the trapping area from a non-baited area, we applied baits at
8 sufficient density to persist for at least 4 days and trapped mice only in the central portion of the
9 baited area.

10 2.4.3.3 Trapping Protocol

11 A 10 by 10 core trapping grid was employed with trap locations spaced 2m apart, making for an
12 18m x 18m core grid. Two nine-inch Sherman live-traps were positioned at each trap location,
13 consisting of a total of 200 traps per grid. Two trap grids were set up, one in the core of each
14 bait density zone. Core grid A was at the center of the 36kg/ha bait zone, and core grid B was at
15 the center of the 27kg/ha bait zone. Live-traps were baited with rolled oats. The distance from
16 the edge of the core to the baited area was at least 50m, approximately double the apparent mean
17 diameter of average mouse home range. We used trap transects to assess the affect of
18 immigration, which is defined as movement into the core area of mice with home ranges outside
19 the baited area. Each transect ran from the edge of the baited core grid through 50m of baited
20 area, to up to 50m beyond the baited area (Figure #). Trap stations were placed in pairs at 10m
21 intervals, totaling 14 traps along immigration transect A and 20 traps along immigration transect
22 B.
23

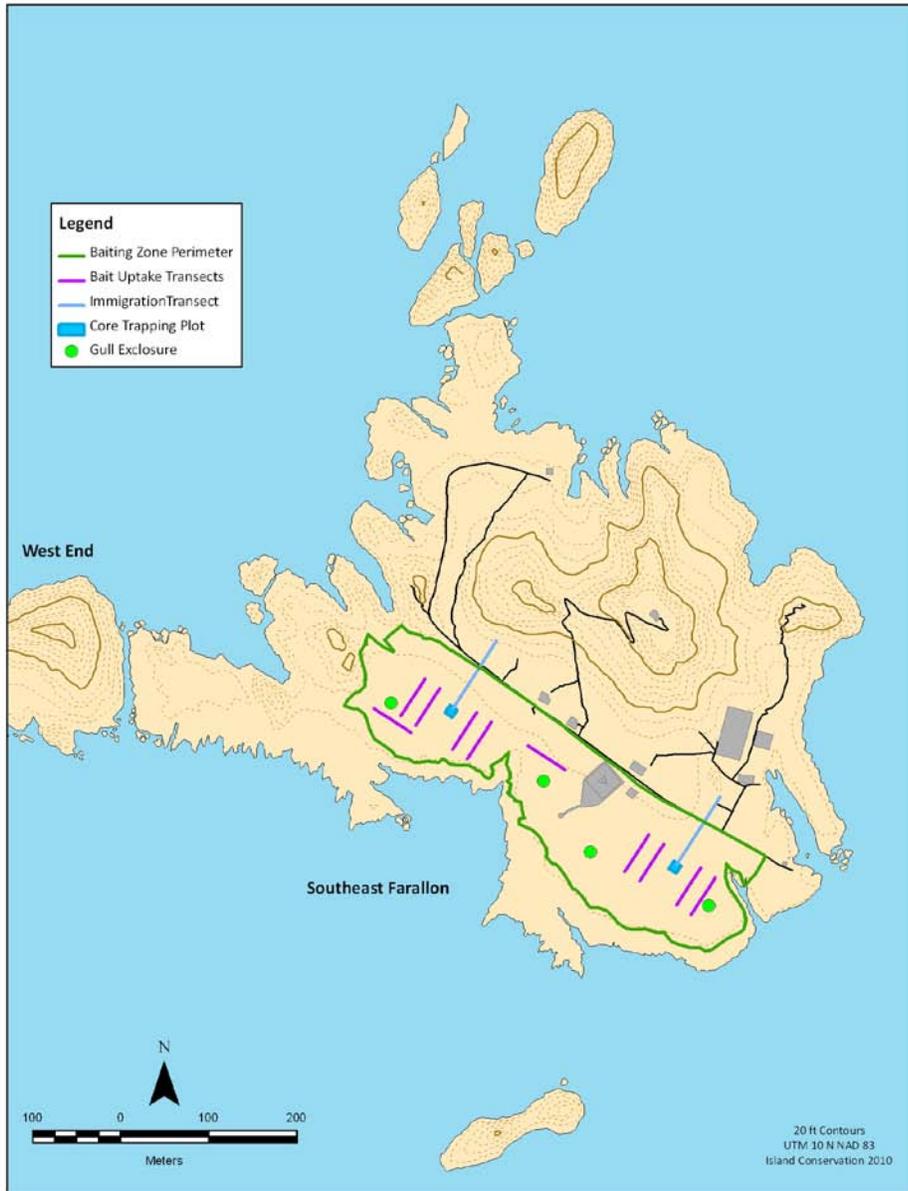

24
25 Traps in both core grids and along immigration transects were set for the first time one day after
26 each of the two bait broadcasting events and checked for two consecutive nights. Morphological
27 measurements and reproductive condition were noted on all captured mice, and all mice were
28 inspected externally with a UV light for exposure to the biomarker. Mice testing positive for bait
29 consumption were euthanized using AVMA-approved methods to simulate a toxic removal from
30 the population, while any mice not showing signs of exposure were released unharmed at the
31 point of capture. Ten percent of the mice testing positive for exposure were set out on the grid
32 and monitored in order to assess the rate of secondary uptake through scavenging of mouse
33 carcasses.
34

35 2.4.3.4 Bait Consumption Rates

36 In order to conduct an effective eradication using brodifacoum, a sufficient amount of toxic bait
37 must be delivered and available to all mice in all territories over at least 4 nights. For this reason
38 it is necessary to measure the amount of bait still present in the environment each day for several
39 days after each application. For the non-toxic trial, bait uptake was measured once per day on
40 ten different uptake plots placed throughout the baited area. Transects were 50m x 1m, with four
41 uptake plots within the 27kg/ha bait plot, and six within the 36kg/ha bait plot (Figure #). The bait
42 in the ten uptake plots were flagged and monitored daily after each application until all bait was
43 consumed. Bait pellet uptake rates were then calculated for each day.
44

Figure ##. Biomarker detection trap areas, and location of bait uptake plots and gull exclusion zones

2. Alternatives

2.4.3.5 Non-target Bait Uptake Monitoring

Because there was concern that bait could be taken up by gulls as well as by mice, four gull exclusion devices were set up within the bait zone and monitored daily for bait uptake to assist in determine the percentage of bait being taken by non-target gulls as opposed to mice. Gull exclusion devices were 2.4m x 2.4m x 0.5m constructed of wood and chicken wire that allowed mice to enter at ground level while eliminating any large birds such as gulls to enter and consume any bait. Two gull exclusion devices were in Study area A and two were in study area B (Figure #). Observations of gulls and other birds within and near the baited zone were also conducted throughout the day to determine approximate numbers on island and to assist in estimating the number of gulls and other non-target species actually foraging on the bait pellets. Two gull fecal plots, one in study area A and one in study area B were also established in two different known roosting areas and were monitored daily to determine the percentage of fecal deposits that tested positive for biomarker.

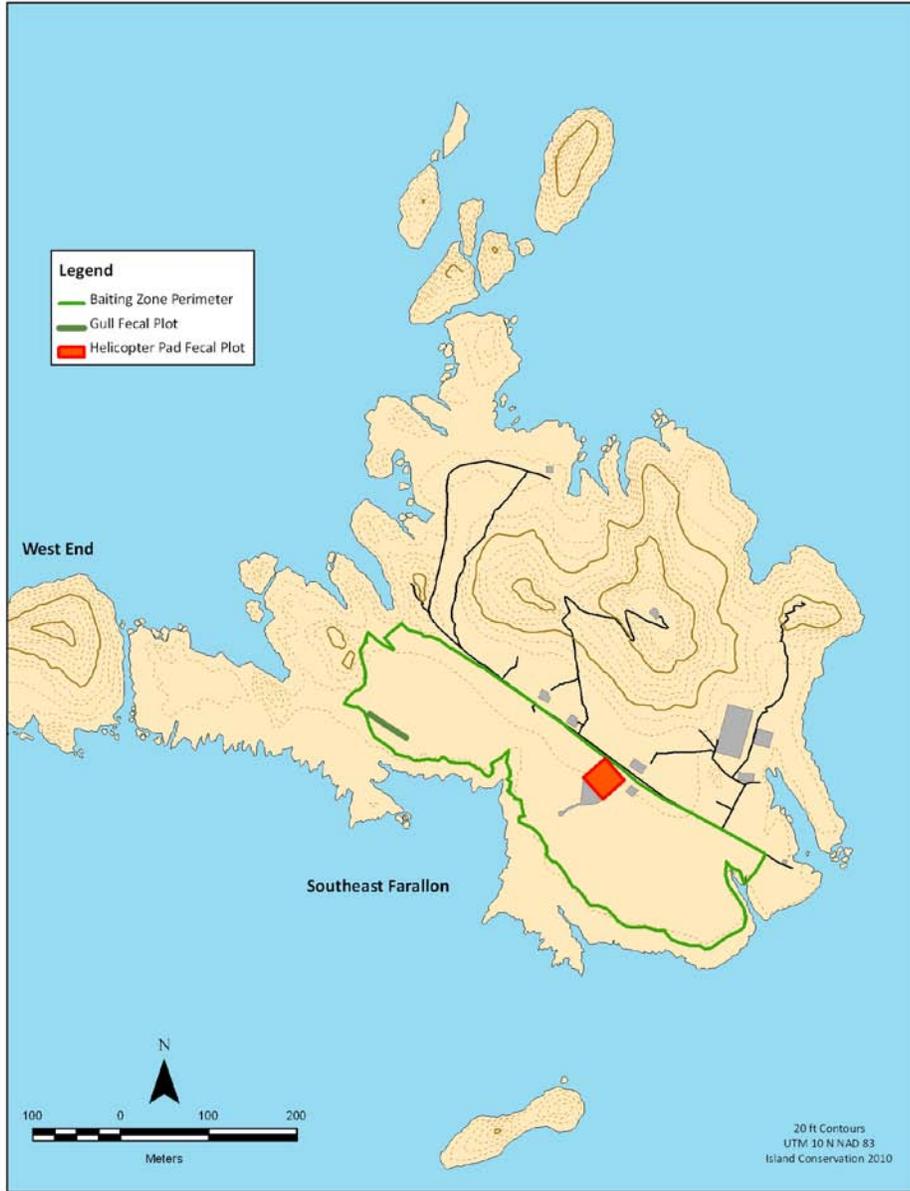

2.4.3.6 Additional Studies Conducted during the Biomarker Trial

A wide variety of other methods were also employed to assess additional variables listed below:

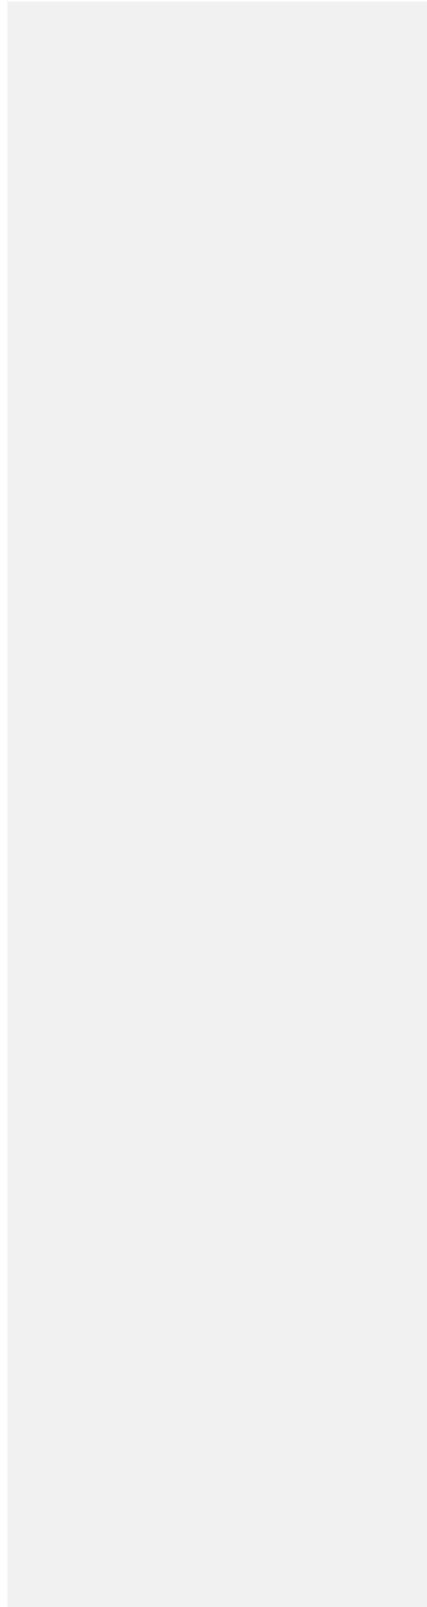

- Bait pellet acceptability and preference by mice
- Biomarker detectability and persistence in mice
- Bait pellet degradation (weathering) studies
- Determine if there is active reproduction ongoing at this time of year
- Rates of bait removal from the environment by mice and gulls
- Detection of biomarker in gulls and burrowing owls and salamanders
- Uptake rates of mouse carcasses euthanized and set to determine secondary uptake rates
- Conduct mice DNA sample collection from both Southeast Farallon and West End
- Detection of biomarker exposure in invertebrates
- Locate and assess caves, coves and areas that may need special bait treatments
- Assess and locate which areas can be treated using bait stations
- Identify and assess treatments that may be used for buildings or other man-made features
- Determine ability to access various portions of the islands and surrounding islets

(See Appendix #XX for a full report on the methods used for each aspect of the trial study).

2.4.4 Summary of Biomarker Trial Results

2.4.4.1 Index of Abundance

Out of 500 possible trap nights (100 traps set for five nights) a total of 434 mice were captured. Trap success averaged 93% on days 2 through 5. The lower trap success the first night (62%) was likely due to less than optimal sensitivity setting of the trap triggers the first evening, rather than any neophobia, based on inspection of the trigger settings on the doors on the first morning. A total of 250 unique individual mice were captured and marked in the trapping period in the 0.25ha area. Recapture rates on nights 2 through 5 were: 35%, 40%, 56% and 66%. The mice were extremely abundant and easily trapped, likely to a combination of high population levels and a scarcity of food resources. Mice were commonly seen foraging throughout the daylight hours, as well as at night. A mouse density estimate is currently being developed using this data, but the raw data alone suggests an extremely high mouse density on the island, as these types of capture rates are rarely reported in the small mammal trapping literature.

2.4.4.2 Bait Efficacy Results

The trap results indicated a high likelihood of bait exposure in mice trapped in the sampled areas. On trap grid A 100% of the mice captured tested positive for biomarker bait consumption after each of the two bait applications. A total of 13 mice were captured in grid A, amounting to ~2% trap success. Area received On grid B mouse trap success rates were much higher, with 25 mice captured after the first application (6.5% trap success), and 129 mice captured after the second bait application (~32% trap success). All 25 mice captured on grid B after the first bait application were positive for biomarker (100% exposure), and on the second trapping 124 of the 129 mice were positive for biomarker, resulting in a 97% exposure rate for that grid on those trap dates.

The few mice not exposed to biomarker in plot B after the second application is likely due to two factors: 1) mice immigrated into the trap grid from outside the biomarker baited area, and/or 2) mice were not exposed to bait due to non-target bait uptake in this area being very high during the days leading up to and following the second bait application. The fact that all five unexposed mice were captured in the northern portion of the bait grid indicates that the mice may have moved in from the unbaited area to the north, which was the only non-baited area within 50m of the bait grid (Figure X). The fact that mouse captures increased by a factor of ten over time in this area indicates a wave of immigration may have occurred. This is supported by the rapid increase in the number of trapped mice on grid B over time, even though those mice testing positive were removed from the population each day. The total number of mice trapped on grid B each night 16 and 9 during the first two trap nights, and 32 and 97 on the next two trap nights, indicating that mice appeared to be moving into the trap zone over time.

Bait uptake by gulls in this area was also very high during this period, however, despite the fact that this area was baited at the higher density of 18kg/ha during the second application as described below in Section 2.4.4.2. It was also noted that non-target (gull) uptake in this area was quite high during the two days preceding the second trapping, leaving considerably less bait available for mice to consume, as described in Section 2.4.4.3.

Immigration transect trapping in both areas A and B revealed positive test results for biomarker in mice captured in traps placed within the bait zone, and a few negative trap results for those

2. Alternatives

5
 6
 7 2.4.4.3 Bait Uptake Results

8 After the first bait application (at 18kg/ha), bait remained on the ground on most of the ten bait
 9 uptake plots for at least four nights, which is the target for eradication purposes. Most of the bait
 10 was gone by Day 5, when the second bait application occurred. Daily bait consumption rates
 11 after the first application were variable among the ten plots and between days, but ranged
 12 between 1.6 to 6.3 kg/ha/day over five days, with a daily average of 3.6kg/day (Figure #XX).

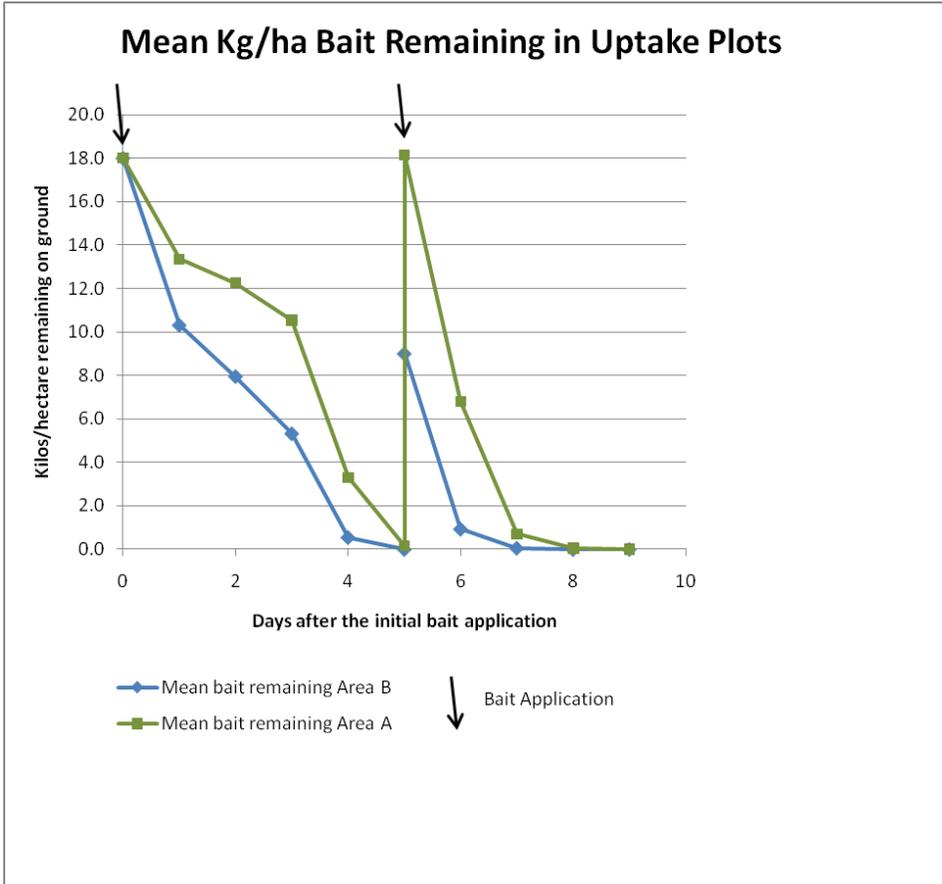

13
 14 The average bait consumption rates per day after the second application was much higher than
 15 the first broadcast, with most bait disappearing from the four uptake plots in the eastern area (B)
 16 within one or two days. Much of this uptake was likely due to the higher abundance of mice in
 17 area B compared to the western study area (A), as mouse capture rates were as high as 49%/day
 18 in area B while area A had at most a 2% trap success rate.

19
 20 On the second application, Area A received twice the amount of bait (18kg/ha) than Area B
 21 (9kg/ha), yet most of the bait on the six uptakes in area A were also consumed in two days as
 22 well. It is likely that some of this consumption was due to non-target uptake of the bait, as by
 23 this time some of the western gulls had learned to identify the pellets as a food item and been
 24 observed foraging for bait heavily in area A, and to a lesser extent in area B (See the following
 25 Section 2.4.4.4 for these results).

2.4.4.4 Trial Non-Target Bait Uptake

The daily uptake monitoring of bait in the four gull exclusion devices demonstrated that gulls were in fact a factor in consuming bait in the bait zone. Bait inside the two gull exclusion devices in Area B was consumed by mice within one to two days, while in the two exclusion devices in area A with relatively fewer mice, the bait lasted for three to four days longer than those immediately adjacent areas where bait was accessible to gulls which were roosting nearby and present in large numbers. Although the small size and number of the exclusion devices limits the ability to extrapolate the results to an island-wide scenario, it is possible that gulls could consume significant amounts of the bait if no avoidance measures are taken.

Comment [DG48]: We will see if we can calculate this %, or present the data in a table or graph of results

2. Alternatives

1 In addition to these pellet counts, 324 hours of visual observations were made of the baited areas
2 each day after baiting over 8 days to determine how many gulls were present in and near the
3 baited zone and how many were observed actually or potentially foraging on the bait. Within a
4 day of the first application less than a dozen western gulls were seen beginning to forage on the
5 bait in a few small areas, but by the second and third days the maximum number of gulls
6 consuming pellets were 118 and 233 total, amounting to 28% to 39% of the gulls in the bait
7 zone. On days 4 and 5 the percentage dropped to 15%, but after the second application of bait on
8 Day 5, the number of pellet-foraging gulls had grown to 153 and 321, representing 34% and 63%
9 of the gulls present in the bait zone. On average, the percentage of gulls foraging on bait during
10 the eight days it was available averaged 27%. The gull foraging behavior on the non-toxic
11 pellets was a learned behavior that seemed to attract additional gulls as they witnessed the
12 foraging motions of nearby gulls. The majority of the gull foraging occurred in the first two
13 hours after sunrise and during the hours preceding sunset. This factor could be useful if applying
14 any gull-avoidance measures during and eradication.
15
16

17 Preliminary trial results indicate that at least 25-50% of the gulls present on island could be at
18 risk during a toxic pellet broadcast unless they were prevented from encountering the bait.
19 Allowing gulls free access to bait would not only result in gull mortalities, but it could have the
20 effect of removing bait that would be necessary to expose all mice on the island to the
21 rodenticide for at least four nights. A successful eradication is one that ensures that every single
22
23

Comment [DG49]: Will need to re-analyze the data for a more accurate estimate

2. Alternatives

1 mouse on the island is exposed to the toxin. The trial results indicate that some form of gull
2 hazing may be necessary to achieving a successful eradication. A gull risk analysis has been
3 contracted that will assess this risk in more detail.

4 2.4.4.5 Gull Counts

6 Island-wide gull counts conducted to estimate the number of gulls on the South Farallon Islands
7 each day during November was highly variable from day to day, ranging from 525 to 3800, and
8 increasing generally with time, as the population shifted from mostly non-breeding intertidal
9 roosting gulls to a larger percentage of territorial breeding birds beginning to spend more time on
10 potential breeding sites throughout the island.

12 A focused gull risk analysis to determine the extent of the risk posed to gulls has been contracted
13 to a team of professional risk analysts familiar with pesticide issues. The results will be
14 discussed in Section 4 and will be provided as an Appendix for the Administrative Draft EA as it
15 becomes available.

Comment [DG50]: Add Avg/mean gull estimates for all SEFI and West End here, and include December as well. (Jan. add later)

Comment [DG51]: Add table/graph here

Comment [DG52]: First Draft Due -Feb. 1

18 2.4.4.6 Additional Trial Results

19 The biomarker trial was very successful in confirming and assessing the trial's major goals. The
20 following generalized results have informed the action alternatives that have been developed:

- 21 A. Mice were exceptionally abundant during the trial, with over 93% trap success, and over
22 250 uniquely marked individual mice captured in a 0.25ha study site over five nights.
- 23 B. While some mice may be able to breed year-round, most mice were not in reproductive
24 condition in November, and most breeding activity appeared to be over at that time.
- 25 C. ~~Mice are having a major impact on the island's resources, eating up to ## kg/year??~~
- 26 D. Mouse abundances on the island are highly variable from site to site.
- 27 E. The ~1g bait pellet size and composition was highly acceptable and palatable by the mice
- 28 F. The EPA registered application rate for brodifacoum of 27kg/ha (delivered at 18 and 9
29 kg/ha) would likely be effective at exposing all mice to bait under certain conditions.
- 30 G. Measures to limit non-target (gull) pellet consumption may be necessary to maintain bait
31 on the ground for the time required for complete exposure to all the mice on the islands.
- 32 H. Some Western gulls would readily learn to eat the bait pellets within several days
- 33 I. That secondary exposure could occur to raptors, ravens and gulls from exposed mice
34 unless mitigation measures were implemented to limit scavenging or predation on mice.
- 35 J. That unconsumed pellets of Conservation 25D would degrade after several rain events
- 36 K. That no exposure to the biomarker was observed in Farallon arboreal salamanders
- 37 L. That island invertebrates have been impacted by the presence and predation by mice
- 38 M. That mice occur on West End and are relatively abundant there as well as on SEFI
- 39 N. That the numerous caves, coves and steep slopes may require special bait treatments
- 40 O. That many areas of steep terrain, or with tidal influences, restricted entry and/or sensitive
41 resources means that parts of the islands could not be treated using bait stations alone.
- 42 P. That the houses, buildings or other man-made features would require special treatment
- 43 Q. That access to various portions of the islands and surrounding islets will need to take into
44 account logistics, wind, waves, tides, weather, and presence of marine mammals.
- 45
- 46

Comment [DG53]: Calculate based on density estimate to be determined.

Comment [DG54]: We should develop the relative abundance data analysis more

Comment [DG55]: Get Gregg Howald to confirm and qualify this conclusion

Comment [DG56]: Add supportive citations

2. Alternatives

- 1 R. That the number and location of roosting gulls and territorial western gulls on the island
- 2 can be quite variable from month to month, day to day, and even hour to hour.
- 3 S. That effective gull hazing measures could reduce the number of gulls exposed to the bait

2.4 Alternative B: Mouse Eradication with Aerial Bait Broadcast as Primary Technique

2.4.1 Rationale for Aerial Bait Broadcast

Employing aerial bait broadcast as the primary bait application method would minimize disturbance to the South Farallones' sensitive terrestrial habitat by allowing the Service to deliver bait to all potential mouse habitats on the island without setting foot on a majority of the landscape. Aerial bait broadcast could be conducted with less than two days of actual helicopter broadcasting, minimizing the length of disturbance to island wildlife. Aerial bait broadcast is also the only safe way to deliver bait to inaccessible terrain such as steep cliffs ~~or within restricted use areas like the designated wilderness~~. Additionally, aerial bait broadcast by helicopter is the preferred bait delivery technique that is currently used most frequently worldwide for island rodent eradications (Howald et al. 2007a).

2. Alternatives

2.4.2 Summary of Bait Delivery Methods

This alternative would involve the use of several bait delivery methods. While the primary method employed would be aerial broadcast, it would also employ bait stations in and around the buildings, water catchment pad, and hand broadcast in selected areas. Figure XX shows which areas would receive which treatment under this alternative.

Comment [DG57]: add this Figure - Alternative B Bait Application Method Map

2.4.2.1 Aerial Application

Bait pellets containing rodenticide would be systematically applied by helicopter to most land areas above the mean high tide mark on the South Farallones. Bait would be applied in two to three applications, separated by 5 to 21 days. Bait would be applied at up to 18kg/ha during the first application, and up to 9kg/ha during the second application. A third treatment would only be conducted if particular areas warranted it, based on bait uptake and the presence of or potential for any continued mouse activity. Helicopter swath width, and would be between 30m to 80m wide, and each swath would overlap the previous swath by 25-50%, depending on swath width, to avoid the risk of gaps in coverage. Bait application rates would be adjusted to account for this overlap. Two types of aerial application swaths would be mapped: a coastal swath up to 60m wide, and a set of parallel interior swaths. On the second application, the parallel flight lines would be run at right angles to the first to take into account variances in bait distribution based on terrain. Each of the two aerial applications could likely be conducted in less than one day.

Comment [DG58]: define these parameters for secondary bait rates and selection of additional bait rates and areas.

Comment [DG59]: Method to reduce superfluous bait drift into these zones where flight lines cross should be discussed more.

In those areas that cannot be baited by helicopter, such as near housing areas, along deeply invaginated coastlines, and over water catchment pads, project staff would distribute bait pellets manually, either by foot, by boat or by hand from the helicopter. The active water catchment pad would be tarped to reduce the possibility of drift into the water supply.

Comment [DG60]: Operational plan would delineate these areas in more detail.

Comment [DG61]: Confirm this method

2.4.2.2 Bait Stations

Project staff would install bait stations in limited circumstances, including within and near residences and outbuildings, in caves, and in more limited areas where bait might be exposed to water or to minimize non-target uptake in selected areas, such as along shorelines. Bait stations would be placed approximately every 5m to 12.5m, and used according to USDA EPA label requirements. Unbaited stations would be placed approximately six weeks prior to baiting, and they would be armed with bait 1-2 days before the first aerial application, and checked every other day for three weeks, and then less frequently (weekly or as needed) to keep them armed. Bait stations would also likely be used in buffer zones around aerial exclusion zones to reduce any gaps in coverage.

Comment [DG62]: Confirm timing specs

2.4.3 Timing

Placement of the unarmed bait stations would occur in early fall, likely in September or October. Aerial broadcast operations would occur in the late fall or early winter, most likely in the months of November and/or December. The actual time period for bait application under the preferred alternative would be defined by the islands' biological patterns and acceptable weather conditions. The period available for bait broadcast would begin after the summer breeding

2. Alternatives

1 season for seabirds, sea lions, and fur seals on the Farallones has ended, and end before female
2 northern elephant seals (*Mirounga angustirostris*) have started giving birth in the early winter
3 (more information on these species is in Chapter 3). Bait broadcast would be completed within
4 this time period, allowing for anticipated weather contingencies. Furthermore, bait broadcast
5 would only be initiated if local weather predictions indicate that precipitation would be unlikely
6 for at least four days. If weather conditions interfere with the scheduled applications, some back-
7 baiting might be required, where treated areas could be retreated.

Comment [DG63]: Build weather contingency into operational plan

Comment [DG64]: (Cite Anacapa EIS-Supplemental)

2.4.4 Equipment and Materials

10 Aerial broadcast operations would be conducted using a single primary-rotor/single tail-rotor
11 helicopter equipped with a specialized bait bucket, known as a hopper, slung beneath, as
12 described in (Section XX).

2.4.5 Bait Application Operations

18 Bait broadcast by helicopter would consist of low-altitude overflights of the majority of the land
19 area of the South Farallones. Each aerial broadcast of bait would likely be completed in one day.
20 Areas within the aerial broadcast exclusion zones would be hand baited or baited with bait
21 stations. These areas include the houses, outbuildings, water catchment, and some highly
22 invaginated shoreline areas and cliffs to minimize drift into the marine environment.

24 Bait stations would be installed in and immediately surrounding all of the buildings and enclosed
25 structures on the island. The bait used in bait stations would be identical to the baited by hand or
26 ~~using bait stations~~. A limited number of bait stations would also be installed elsewhere on the
27 island as necessary. The bait stations would have the design specifications listed in Section 2.4.4.

2.4.6 Project Support Operations

32 In addition to applying bait, helicopters would be used to transport equipment and personnel to
33 the island for the purpose of this action. These additional helicopter operations would be
34 localized to discrete flight paths that would be determined so as to minimize disturbance to
35 native wildlife. Helicopters may hover for brief periods over land to drop off personnel and
36 equipment.

38 Helicopters may be staged from the island or from a boat offshore of the island. Helicopters
39 would only land at designated staging areas, where staff would re-fill the bait hopper, re-fuel,
40 and conduct other necessary maintenance. These staging areas would be adequately stocked with
41 fuel and other supplies and equipment to support the helicopter for the entire bait application
42 process.

2.4.7 Mitigation Measures

2. Alternatives

Mitigation measures to be used in this and all other action alternatives are similar and have been described in Section 2.2, but there are differences in when, where and how the mitigation measures will be employed.

Some non-target bird species may be exposed to the bait either directly by consuming the bait pellets or indirectly by consuming mice or other organisms that have eaten the bait. A fraction of the resident raptors and gulls on the island at the time of the application may experience exposure to the bait without some form of specific efforts to avoid such exposure.

Mitigation Measures to be employed for this and all action alternatives would include:

- **Timing:** Conducting the operation at a time of year when the resident seabird, shorebird and land-bird populations are at their lowest.
- **Carcass removal:** Dead mice, birds or any other animal found that is suspected of having succumbed to the toxicant, will be removed when found to reduce the likelihood of secondary exposure in scavengers;
- **Burrowing owl capture and relocation:** Efforts will be made to capture the transient burrowing owls arriving on island and to hold and release them on the mainland, as the Service has done in the past, to reduce the risk of toxicant exposure; and
- **Capture, hold and release efforts for other resident and migrating raptors:** The resident pair of Peregrine falcons and Common ravens (*Corvus corax*), and possibly other migrating raptors may be captured and removed until the Service determines the birds would no longer be at risk of exposure to toxicant;
- **Gull hazing:** Attempts will be made to reduce gull pellet consumption and non-target mortality by utilizing techniques developed and tested during a January 2011 hazing trial.
- **Use of bait stations:** In areas with particularly high concentrations of roosting gulls to reduce gull uptake of bait.

Pinniped disturbance reduction methods used for this alternative:

- **Timing:** Conducting the operation and before and after the pinniped pupping seasons;
- **Crouching** or crawling when necessary to remain out of view of nearby animals;
- **Moving slowly** and deliberately to avoid frightening animals while traveling by foot;
- **Avoiding sensitive areas** when possible to reduce disturbance to haul-out sites;
- **Education and Training:** All staff would be shown maps detailing areas with sensitive wildlife and trained on how to avoid disturbing wildlife and avoiding impacts to sensitive habitats such as nesting burrows and crevices. These sensitive wildlife areas are fully described in Section 3.

Addition mitigation: Alternative B will also employ the use of a controlled surveillance flight with a PRBO marine biologist prior to any aerial bait applications. Although none will likely be breeding during the aerial application window, pinnipeds will likely still be present in potentially large numbers during the late fall and early winter. In order to reduce the risk of unpredictable and potentially harmful disturbance to pinnipeds from helicopter operations, the helicopter pilot

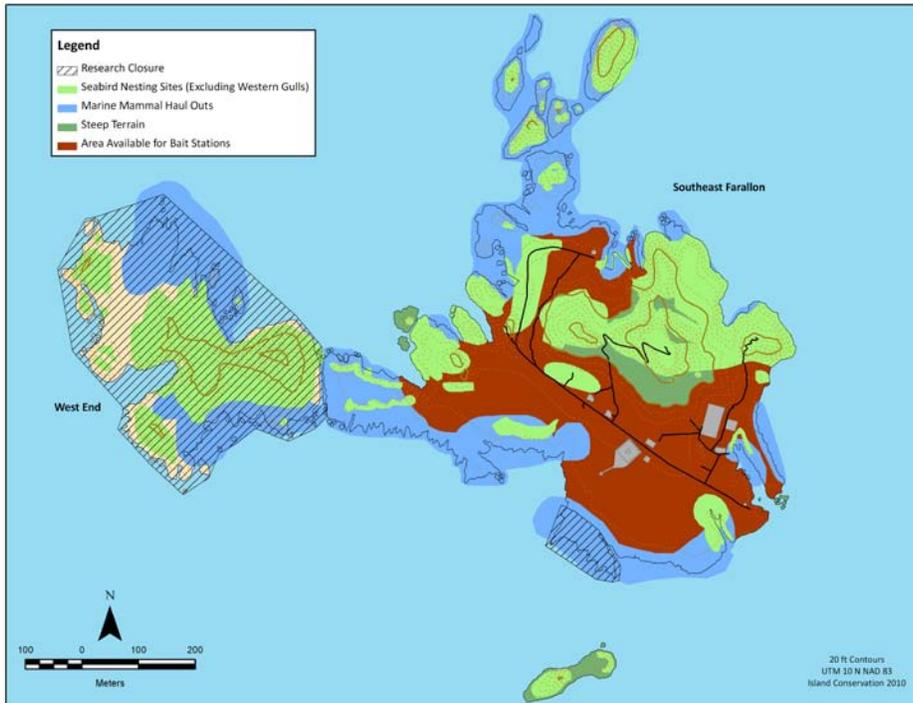

2. Alternatives

1 would conduct a controlled surveillance flight around the coastline before bait operations begin
2 in which pinniped haulout locations are noted. During this surveillance flight, an experienced
3 pilot would approach major haulout sites with the intention of exposing hauled out animals to a
4 gradual auditory and visual disturbance similar to the bait application. This controlled “dry run”
5 would likely enable the animals to become aware of the helicopter and then move off of major
6 haulouts into the water, which would allow the helicopter to treat coastal areas immediately
7 afterward while most pinnipeds are still in the water rather than hauled out again. This approach
8 would reduce the risk of a stampede among hauled out animals, thus reducing their risk of injury.
9 This technique was successfully employed in both the Anacapa Island treatment and the Rat
10 Island treatment in the USFWS Alaska Maritime Wildlife Refuge (Citation).

Comment [DG65]: Add citation proper

ADMINISTRATIVE REVIEW DRAFT

2. Alternatives

2.5 Alternative C: Bait Station Delivery as Primary Technique

2.5.1 Rationale for Bait Stations

Using bait stations as the primary bait application method would reduce the risk that birds or other non-target species would be exposed to the rodenticide, and reduce the total amount of rodenticide introduced to the environment. Using bait stations would also reduce the extent of helicopter operations over the South Farallones. Bait station delivery was historically the first method of island rodent eradication, and it remains common today (Bell 2002, Burbidge and Morris 2002, Hayes et al. 2004, Clout and Russell 2006, Howald et al. 2007a).

It would be nearly impossible to conduct a successful mouse eradication operation using bait stations exclusively, and to date there has only been one successful mouse eradication only using a bait station technique (Citation). Therefore, under this alternative, the Service will treat inaccessible areas such as cliffs and unstable slopes by hand or by aerial broadcast. The primary rationale for using bait stations is to reduce the overall non-target risk for the majority of the islands biological resources. Unfortunately, a bait station operation would need to be installed and revisited every other day for several months, which could cause unacceptable impacts to

Comment [DG66]: Get citation

2. Alternatives

1 breeding birds and marine mammals in many areas, so that these sensitive resource areas would
2 require aerial baiting as well to limit the human activity over large areas of habitat. Furthermore,
3 a large percentage of the area (West End) is designated wilderness making much of the island
4 almost entirely untreatable in this manner. Those areas that could conceivably be treated by bait
5 station total 15-20? hectares and are shown in red in Figure XX.
6
7

2.5.2 Summary of Bait Delivery Methods

8
9
10 Enclosed bait stations would be installed every 5m - 12.5m in a grid pattern across the majority
11 of the accessible land area on the South Farallones. In areas that cannot be included in the bait
12 station grid, such as cliffs, unstable slopes, and critically sensitive habitat, bait pellets containing
13 rodenticide would be spread by helicopter or by hand. In all areas where bait stations can be
14 safely installed and major impacts to terrestrial habitat (such as seabird disturbance, dislodging
15 of rocks, or erosion) can be avoided or minimized, bait stations would always be the preferred
16 technique under this alternative. Bait stations would also be installed within and near residences
17 and outbuildings.
18
19

2.5.3 Timing

20
21
22 Initially bait station installation would begin in the fall after the peak seabird fledging season in
23 September or October. Bait stations would be set out six weeks prior to being armed, and armed
24 one to two days before aerial operations. Areas that are not included in bait station coverage
25 would be baited by hand and helicopter in the late fall or early winter according to the timing
26 specifications described in Alternative B (Section 2.3.3). The use of bait stations in Alternative C
27 would entail at least a year of maintaining the bait stations. This sequence of operations would be
28 particularly important for Alternative C because bait would only be available in broadcast-treated
29 areas for a limited period of time, thus it would be essential to eradicate mice from adjacent bait
30 station-treated areas before broadcast treatment is initiated to eliminate the possibility that mice
31 could migrate from station-treated areas into broadcast-treated areas after all the broadcast bait
32 had disappeared.
33

Comment [DG67]: Confirm length of bait station operation.

Comment [DG68]: This is the main reason this Alternative method has a lower chance of success. It also requires many more people and hours on foot in breeding areas all year long.

2.5.4 Equipment and Materials

34
35
36 Bait stations are box-like enclosures with small entryways designed to be attractive to rodents
37 but difficult to navigate for other species such as birds. Bait stations reduce the risk of
38 rodenticide exposure in non-target species by making bait more difficult to access and reducing
39 the total amount of bait introduced into the ecosystem.
40

41 Since bait stations would need to be accessed frequently during bait dispersal, the Service would
42 have to ensure that there is sufficient access ~~would have to be ensured~~ to each bait station. In
43 some cases no landscape modifications would be necessary; however, depending on the local
44 placement of each station, a number of landscape modifications and/or installations may be
45 necessary to properly secure bait stations into place. Examples of these modifications could
46 include:

2. Alternatives

- Paths cut through vegetation for stability;
- Installation of boardwalks to avoid trampling seabird burrows or other sensitive resources;
- Anchor points, ladders, and fixed lines to allow for safe access to bait stations placed on steep and/or unstable terrain.
- Some bait stations may also require modification (i.e. additional covering) to prevent rain or moisture from entering the box and damaging the bait.

Some access pathways may need to be crossed especially in sensitive habitat such as areas with seabird nest burrows and rocky talus slopes that harbor seabird nest crevice habitat. Whenever possible, access paths would be routed around sensitive biological habitat, or temporary platforms, walkways, or other temporary infrastructures would be installed to avoid trampling.

Each bait station would be secured to the ground with anchors placed into the soil or drilled into the rock as appropriate. The infrastructure required for the bait station grid would be durable enough to withstand the corrosive marine environment of the Farallones for up to two years, but it would be removable and not a permanent fixture on the islands.

Any areas in which bait station installation and maintenance would be extremely difficult (e.g. cliff areas) would be treated with a hand or aerial bait broadcast to ensure that all rodents on the island have access to the bait. The helicopter, hopper, bait and bait station that would be used are the same for all action alternatives, but the number of bait stations required for this alternative would be substantially larger than the other two alternatives.

Approximately 15-20 hectares of land would need to be baited with bait stations under this alternative, with potentially one bait station every 5m, amounting to up to 10,000 stations, with an additional xx stations required in and around the houses, outbuildings, caves, shorelines, and dense gull roost and/or haul-out areas.

Comment [DG69]: Revise figure based on calculated acreage.

Comment [DG70]: Need to discuss this strategy based on uptake, crushing of bait, and MM disturbances

2.5.5 Bait Delivery Operations

Bait stations would be placed on a grid that covers those portions of the islands potentially accessible on foot (Figure XX). To maximize the probability of delivering bait to each and every mouse, station spacing should be 5 to 12.5m apart. The total land area of the South Farallones is 120 acres (49 ha), but at least 70 percent of that land area would be excluded from the bait station grid. Assuming, then, that a bait station grid would cover 20 ha, a 10 m spacing would require an estimated 2000 individual bait stations, and 5m spacing would require an estimated 8,000 stations. These stations would need to be visited every other day for XX days, requiring considerably more personnel than other alternatives and resultant repeated foot traffic on the island.

Comment [DG71]: Amend figure using planar or surface area figures?

Comment [DG72]: Get new #s based on %

The design and location of the bait station grids would be adaptive. The grid pattern would need to be carefully designed and installed taking the complex topography of the island into account – cliffs and highly unstable slopes would be identified during on-site surveys, mapped, and

2. Alternatives

1 excluded from bait station grids. For all areas in which bait stations could be safely installed, the
2 Service would choose bait stations over hand or aerially broadcasting bait, with two exceptions:

- 3 7. When the Service determines that bait stations in specific sites would likely cause major
4 negative impacts to sensitive species such as seabirds and pinnipeds, bait may be
5 broadcast instead, either by hand or by helicopter. When designing the bait station grid,
6 however, the Service would need to prioritize the relative ecological importance of
7 avoiding disturbance to seabirds nesting in different sections of the island, with the
8 recognition that in order to cover greater than 50 percent of the island, thousands of
9 seabirds would likely need to be disturbed.
- 10 8. In Designated Wilderness, the Service would choose hand or aerial broadcast before bait
11 station operations in wilderness areas where bait station installation would require
12 greater-than-normal habitat modification such as extra anchors or breaking rocks.

13
14 Each bait station would be armed with bait pellets as soon as possible once the program is
15 initiated. Each station would be visited daily or on alternate days, checked, and bait replenished
16 as necessary until activity ceases (activity includes bait chewed or taken by mice). Project crew
17 would collect data (number of pellets taken, chewed, added, or replaced) from each station and
18 enter it into a database for analysis. Bait application rates would be adjusted, if necessary, in
19 response to these data to ensure that bait is always available to mice throughout the bait station
20 grid. Bait stations would be loaded with bait immediately after installation and checked and re-
21 armed frequently. When activity (bait removal or consumption) ceases, bait stations would be
22 checked and re-armed bi-weekly then monthly for another full mouse breeding cycle,
23 documenting bait take and mouse sign in stations. Bait station visit rates would be modified
24 based on uptake rates.

25
26 Any areas of the South Farallones that cannot be treated within the bait station grid would be
27 treated by bait broadcast. Whenever feasible, hand broadcast would be conducted by foot or by
28 boat, but some inaccessible or critically sensitive areas would require the use of a helicopter.
29 Helicopter broadcast methods and considerations in Alternative C would be to the same as those
30 described in Alternative B, (Section 2.3). The borders of broadcast and bait station treatment
31 areas would need to overlap to ensure adequate bait delivery in the transition zone between
32 treatment areas. As described above in Section 2.4.3, the sequence of implementation would be
33 important. In addition to the seasonal timing requirements of aerial broadcast described in
34 (Section 2.3.3), bait broadcast operations would be further constrained because broadcasting
35 would not start until the Service no longer detects mice within the core of the bait station grids.
36 This will likely take at least four weeks from the time bait stations are first armed and possibly as
37 long as three months after arming.

38
39 Bait stations would also be installed in and immediately surrounding all of the buildings and
40 enclosed structures on the island.

41
42 All personnel that handle bait or monitor bait application in the field would meet or exceed all
43 requirements for personal protective equipment (PPE) required by the EPA. All bait application
44 activities (aerial broadcast, hand broadcast, and bait station filling) would be conducted by or
45 under the supervision of pesticide applicators licensed by the State of California.

Comment [g73]: This will need to be modified to reflect the slowdown in bait taken. Look at Palmyra EIS for some insight.

Comment [DG74]: Review Alternative C Map for accuracy of sensitive resource areas where no bait-stations will be allowable/possible.

Comment [DG75]: Confirm that bait overlap is allowed by label ...ask Gregg Howald

2. Alternatives

2.5.6. Project Support Operations

Helicopters would also be used to transport equipment and supplies, including the bait and bait stations that will be installed, to the island for the purpose of this action. These additional helicopter operations would be localized to discrete flight paths that would be determined so as to minimize disturbance to native wildlife. Helicopters may hover for brief periods over land to drop off personnel and equipment.

Helicopters may be staged from the island or from a boat offshore of the island. Helicopters would only land at designated staging areas, where staff would re-fill the bait hopper, re-fuel, and conduct other necessary maintenance. These staging areas would be adequately stocked with fuel and other supplies and equipment to support the helicopters for the entire bait application process.

The personnel required for bait station maintenance would join the PRBO researchers that live on-island year-round, using the residential facilities and infrastructure already in place, as well as limited additional storage and staging space on already-modified land.

2.5.7. Mitigation Measures

Mitigation measures to be used in this and all other action alternatives are similar and have been described in (Section 2.2), but there are differences as to when, where and how extensively the mitigation measures will be employed. Impacts are defined as either non-target consumption or disturbances.

Some non-target bird species may be exposed to the bait either directly by consuming the bait pellets or indirectly by consuming mice or other organisms that have eaten the bait. A fraction of the resident raptors and gulls on the island at the time of the application may experience exposure to the bait without some form of specific efforts to avoid such exposure.

Bird mortality reduction methods to be employed for this and all action alternatives include:

- **Timing:** Conducting the operation at a time of year when the resident seabird, shorebird and land bird populations are at their lowest levels.
- **Carcass removal:** Dead mice, birds or any other animal found that is suspected of having succumbed to the toxicant will be removed when found to reduce the likelihood of secondary exposure in scavengers;
- **Burrowing owl capture and relocation:** Efforts will be made to capture the transient burrowing owls arriving on island and to hold and release them on the mainland, as the Service has done in the past, to reduce the risk of toxicant exposure; and
- **Capture, hold and release efforts for other resident and migrating raptors:** The resident pair of Peregrine falcons and Common ravens (*Corvus corax*), and possibly other

2. Alternatives

1 migrating raptors may be captured and removed until the Service determines the birds
2 would no longer be at risk of exposure to toxicant;

- 3 • **Gull hazing:** Attempts will be made to reduce gull pellet consumption and non-target
4 mortality by utilizing techniques developed and tested during a January 2011 hazing trial.
- 5 • **Use of bait stations:** In areas with particularly high concentrations of roosting gulls to
6 reduce gull uptake of bait.

7
8 Although supplemental bait broadcast under Alternative C would occur outside of any pinniped
9 breeding activities, there are still many pinnipeds present during the late fall to early winter time
10 period identified. The Service would follow the mitigation requirements described in Section
11 2.4.7 to reduce the risk of harmful disturbance to these pinnipeds.

13 Pinniped disturbance reduction methods used for this alternative:

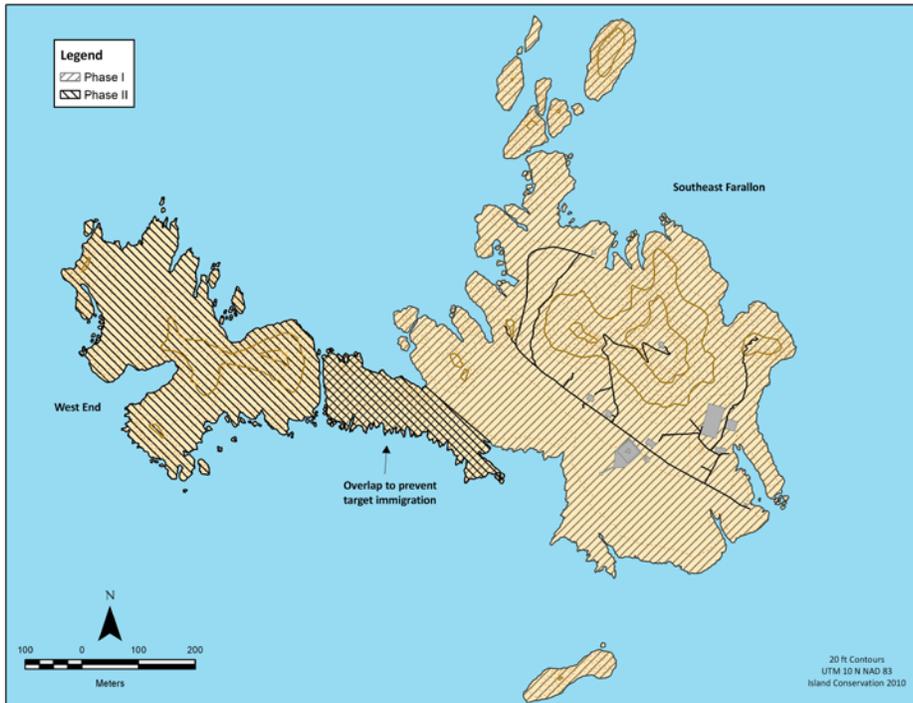

- 14
- 15 • **Timing:** Conducting the operation largely outside of any pinniped pupping seasons;
- 16 • **Crouching** or crawling when necessary to remain out of view of nearby animals;
- 17 • **Moving slowly** and deliberately to avoid frightening animals while traveling by foot
- 18 • **Avoiding sensitive areas** when possible to reduce disturbance to haul-out sites
- 19 • **Education and Training:** All staff would be shown maps detailing areas with sensitive
20 wildlife and trained on how to avoid disturbing wildlife and avoiding impacts to sensitive
21 habitats such as nesting burrows and crevices. These sensitive wildlife areas are fully
22 described in Section 3.

23
24 **Addition mitigation:** Alternative C will also employ the use of a controlled surveillance flight
25 with a PRBO marine biologist prior to any aerial bait applications. Although none will likely be
26 breeding during the aerial application window, pinnipeds will likely still be present in potentially
27 large numbers during the late fall and early winter. In order to reduce the risk of unpredictable
28 and potentially harmful disturbance to pinnipeds from helicopter operations, the helicopter pilot
29 would conduct a controlled surveillance flight around the coastline before bait operations begin
30 in which pinniped haulout locations are noted. During this surveillance flight, an experienced
31 pilot would approach major haulout sites with the intention of exposing hauled out animals to a
32 gradual auditory and visual disturbance similar to the bait application. This controlled “dry run”
33 would likely enable the animals to become aware of the helicopter and then move off of major
34 haulouts into the water, which would allow the helicopter to treat coastal areas immediately
35 afterward while most pinnipeds are still in the water rather than hauled out again. This approach
36 would reduce the risk of a stampede among hauled out animals, thus reducing their risk of injury.
37 This technique was successfully employed in both the Anacapa Island treatment and the Rat
38 Island treatment in the USFWS Alaska Maritime Wildlife Refuge (Citation).

Comment [DG76]: Add citation

39
40 The Service would first aim to avoid negative impacts to pinnipeds by timing activities to occur
41 outside of sensitive breeding and molting seasons. However, under Alternative C the
42 maintenance of bait stations would need to continue over at least one year, which would overlap
43 with the breeding seasons of all pinnipeds on the islands. In order to minimize disturbance to
44 pinnipeds, the bait station grids would be designed to be out of sight of large concentrations of
45 pinnipeds. In particular, the bait station grid would avoid known breeding sites for the threatened
46 Steller sea lion (*Eumetopias jubatus*) to reduce disturbance.

2. Alternatives

2.6. Alternative D: Phased Aerial Bait Broadcast as Primary Technique

2.6.1. Rationale for Phased Aerial Bait Broadcast

This alternative is very similar to Alternative B (Section 2.4) except that the two main islands of the South Farallones (West End and Southeast Farallon) would be baited aurally approximately two to six weeks apart in order to provide the remaining birds and pinnipeds present in the fall with nearby undisturbed roost and haul-out sites on one island while the other is being aurally treated. This alternative would involve more intensive non-target hazing efforts than the other two action alternatives. In order to reduce non-target uptake of bait by roosting gulls, they would be intentionally hazed off of the treated island just prior to bait application, and allowing them to roost undisturbed on immediately adjacent nearby islands. After approximately two to six weeks, they would then be allowed to roost and haul out on the treated island, while the other island is hazed of gulls and then baited aurally. This alternative would also provide the marine mammals with at least one undisturbed island to haul out onto during the duration of the operation. This alternative also has the effect of both reducing impacts to non-target species as well as maximizing the ability to expose all of the mice on each island to the toxicant. Both gulls eating bait and pinnipeds rolling over bait could reduce the amount of bait available to mice in areas of dense roosts and haul-outs. The only drawbacks to this method are: 1) the time-lag might

Comment [DG77]: Timing could be modified

2. Alternatives

1 increase the chance that the first treated island could be re-colonized by mice before the second
2 island is treated; and 2) a more intensive initial IHA will be required to allow for intentional
3 disturbances to marine mammals so they can be slowly herded off the targeted island.

4
5 As with Alternative B, utilizing aerial bait broadcast as the primary bait application method
6 would minimize disturbance to the South Farallones' sensitive terrestrial habitat by allowing the
7 Service to deliver bait to all potential mouse habitats on the island without setting foot on a
8 majority of the landscape. Aerial bait broadcast is also the only safe way to deliver bait to
9 inaccessible terrain such as steep cliffs or within restricted use areas like the designated
10 wilderness. Additionally, aerial bait broadcast by helicopter is the preferred bait delivery
11 technique that is currently used most frequently worldwide for island rodent eradications
12 (Howald et al. 2007a).

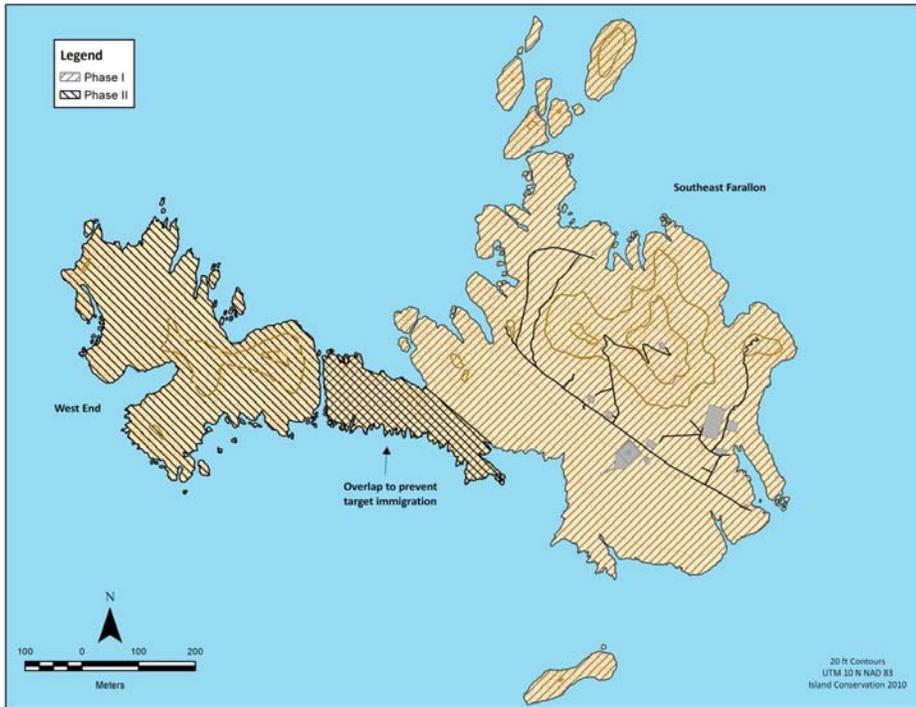

2.6.2. Summary of Bait Delivery Methods

13
14
15
16
17 This alternative would involve the use of several bait delivery methods. While the primary
18 method employed would be aerial broadcast, it would also employ bait stations, as well as hand
19 broadcast. Figure XX shows which areas would receive which treatment under this alternative.
20 The primary difference with alternative D involves the phasing of the application of bait on
21 Southeast Farallone and West End Island, as shown in Figure XX.

Comment [DG78]: Add Figure XX Map here

Comment [DG79]: Add Map of Figure XX

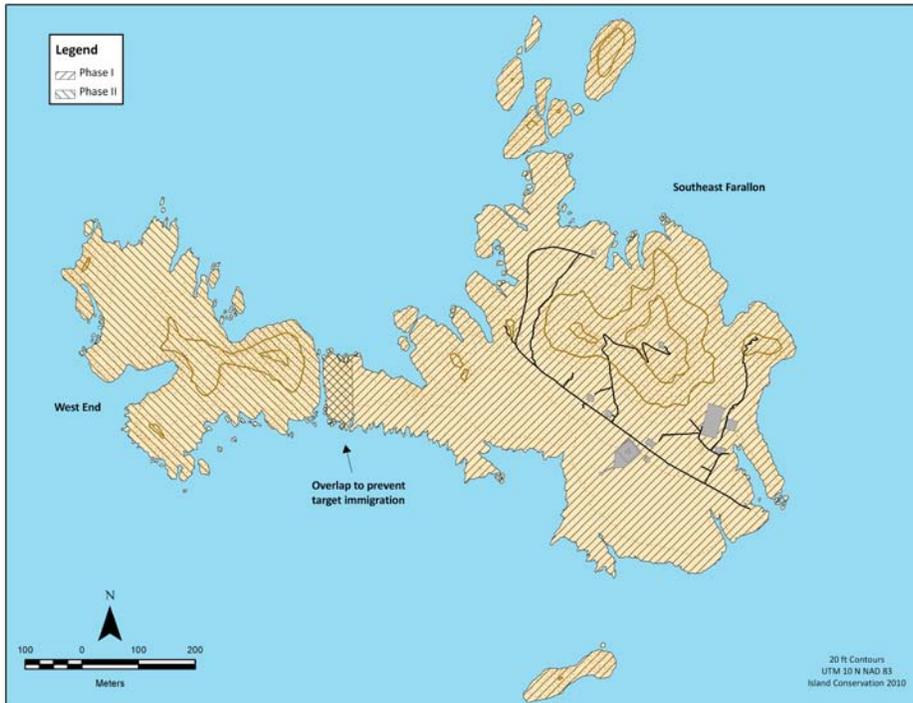

2. Alternatives

1

ADMINISTRATIVE

2. Alternatives

1
2
3 *The Figures above represent two baiting configurations currently being considered for the*
4 *phased option in Alternative D. The first represents a more conservative approach with more*
5 *overlap to reduce the likelihood of recolonization by mice between baiting when the two*
6 *phases of the operation are further apart in time;*

7 *The second with minimal overlap represents a strategy that could be employed if there were*
8 *very little time between phases, although this poses a much greater risk of recolonization as*
9 *mice may pass through the narrow baited zone without consuming a lethal dose of bait.*

10 *I included this second figure more out of concern for avoiding non-target gulls and pinnipeds*
11 *in the larger peninsular area, and as a point for discussion of this topic.*

15 2.6.2.1 Aerial Application

16 Bait pellets containing rodenticide would be systematically applied by helicopter to most land
17 areas above the mean high tide mark on the South Farallones, first on Southeast Farallone, and
18 then on West End. Bait pellets containing rodenticide would be systematically applied by
19 helicopter to most land areas above the mean high tide mark on the South Farallones. Bait would
20 be applied in two to three applications, separated by 5 to 21 days. Bait would be applied at up to
21 18kg/ha during the first application, and up to 9kg/ha during the second application. A third

2. Alternatives

1 treatment would only be conducted if particular areas warranted it, based on bait uptake and the
2 potential for any continued mouse activity.

3
4 Helicopter swath width, ~~and~~ would be between 30m to 80m wide, and each swath would overlap
5 the previous swath by 25-50%, depending on swath width, to avoid the risk of gaps in coverage.
6 Bait application rates would be adjusted to account for this overlap. Two types of aerial
7 application swaths would be mapped: a coastal swath up to 60m wide, and a set of parallel
8 interior swaths. On the second application, the parallel flight lines would be run at right angles
9 to the first to take into account variances in bait distribution based on terrain. Each of the two
10 aerial applications could likely be conducted in less than one day.

11 2.6.2.2 Bait Stations

12 Project staff would install bait stations in limited circumstances, including within and near
13 residences and outbuildings, in caves, and in more limited areas where bait might be exposed to
14 water or to minimize non-target uptake in selected areas, such as along shorelines. Bait stations
15 would be placed approximately every 5m to 12.5m, and used according to USDA EPA label
16 requirements. Unbaited stations would be placed approximately six weeks prior to baiting, and
17 they would be armed with bait 1-2 days before the first aerial application, and checked every
18 other day for three weeks, and then less frequently (weekly or as needed) to keep them armed.
19 Bait stations would also likely be used in buffer zones around aerial exclusion zones to reduce
20 any gaps in coverage. In those areas near the water catchment pads, project staff would distribute
21 bait pellets manually or use bait stations.
22

23
24 A strip of habitat on the southwestern portion of Southeast Farallon Island would be baited at the
25 same time as West End, so as to reduce the likelihood of mice in this area crossing the Jordan
26 Channel and recolonizing West End while SEFI is being treated. Bait stations may be used in
27 this area as well as hand and aerial broadcast in order to ensure proper bait density applications.
28 Use of supplemental bait stations in this area may be useful to reduce uptake by any nearby gulls
29 and may reduce the crushing of bait by any pinnipeds attempting to haul out in this area. This
30 strip has relatively high densities of roosting gulls and marine mammals hauling out.
31

32 2.6.3. Timing

33
34 Although the baiting of the two main islands would be phased approximately two to six weeks
35 apart, the aerial broadcast operations would still occur in the late fall or early winter, most likely
36 in the months of November and/or December, just as in Alternative B. The actual time period for
37 bait application would be defined by the islands' biological patterns and prevailing weather
38 patterns. The period available for bait broadcast would begin after the summer breeding season
39 for seabirds, sea lions, and fur seals on the Farallones has ended, and end before female northern
40 elephant seals (*Mirounga angustirostris*) have started giving birth in the early winter (more
41 information on these species is in Chapter 3). Bait broadcast would be completed within this time
42 period, allowing for anticipated weather contingencies. Furthermore, bait broadcast would only
43 be initiated if local weather predictions indicate that precipitation would be unlikely for at least
44 four days. If weather conditions interfere with the scheduled applications, some back-baiting
45 might be required, where treated areas could be retreated.

Comment [DG80]: Confirm timing specs

Comment [DG81]: Need to discuss the area of overlap in more detail, and how to avoid going over EPA label restrictions

Comment [DG82]: (Cite Anacapa EIS.- Supplemental)

2. Alternatives

2.6.4. Equipment and Materials

As with alternative B and C, bait broadcast operations for alternative D would be conducted aurally using a single primary-rotor/single tail-rotor helicopter, by hand or using bait stations. The bait would be a compressed grain pellet, ~1.1 g in weight, containing 25 parts per million (ppm) brodifacoum, which is a second-generation anticoagulant. The bait used would be registered with the EPA and in compliance with the Federal Insecticide, Fungicide and Rodenticide Act (FIFRA). The bait product would be designed to be highly attractive to mice. All other ingredients in bait pellets would be non-germinating grains (either sterile or crushed). Any bait not initially consumed would likely remain attractive to mice. However, the bait would disintegrate completely within one or two major rainfall events.

2.6.5. Bait Application Operations

Bait broadcast by helicopter would consist of low-altitude overflights of the majority of the land area of the South Farallones. Bait broadcast would be very similar to that described in Alternative B (Section 2.2), using a helicopter with low-altitude overflights of most of the land area of the South Farallones. The only major difference would be that Southeast Farallone would be aurally treated first, and approximately two to six weeks later West End would be aurally treated. Each island would require two aerial applications, approximately 5 to 21 days apart. Each aerial broadcast of bait would likely be completed in one day. A small area of the west side of Southeast Farallone would remain baited throughout the operation to reduce the likelihood of a reinvasion between islands in between the two operations.

Prior to aerial application, the gulls roosting on the targeted island would be selectively and carefully hazed off their roosts utilizing lasers and a variety of additional visual and auditory hazing techniques that have been shown effective for roosting gulls at airports and reservoirs in the U.S. and around the world. Specific gull hazing techniques for this alternative are being developed and tested in a January 2011 hazing trial, in association with the USDA bird hazing program and the Oiled Wildlife Care Network with CDFG and UC-Davis.

In addition to providing a refuge for the gulls, this alternative would also marine mammals a place to remain hauled out in the area while baiting and gull-hazing operations are ongoing on the other island. Alternative D would also employ slowly approaching helicopters for the pinnipeds, so as to ensure a slow and cautious but thorough emptying of the targeted area. Slow herding by land-based personnel may be required as well to ensure no marine mammals are stranded.

After the haulouts are emptied, temporary (plywood and 2"x4") fencing may be installed at the haul-out access points to inhibit them from returning to that site for the duration of the application (~2-6 weeks) so as to ensure no unnecessary additional disturbances to them during the duration of the baiting procedures.

Comment [DG83]: Confirm date ranges

Comment [DG84]: Cite OSPR and manual and the draft gull hazing study plan

Comment [DG85]: We need to discuss whether to use this access-reducing measure, and how much to employ careful but intentional hazing on the pinnipeds themselves, versus purely incidental harassment.

2. Alternatives

1 After most of the non-target species that can be hazed have left the bait zone, ~~and~~ then the aerial
2 application can begin in that area. The aerial bait application would consist of a helicopter flying
3 at a speed ranging from 25-50 knots (29-58 mph or 46-93 km/hr) at an average altitude of
4 approximately 164 ft. (50 m) above the ground, with the bait hopper long-lined 49-66 ft (15-20
5 m), as in Alternative B. The bait would be applied according to a flight plan that would take into
6 account:

- 7 • The need to apply bait relatively evenly and to prevent any gaps in coverage or excessive
8 overlap;
- 9 • Island topography to reduce pooling at the base of steep slopes;
- 10 • The distribution of roosting seabirds on the adjacent islands, especially western gull and
11 common murre (*Uria aalge*);
- 12 • The need to avoid bait broadcast into the marine environment;
- 13 • The need to minimize disturbance to native wildlife, especially any pinnipeds hauled out
14 on the adjacent island(s);
- 15 • The need to avoid bait broadcast into residential areas;
- 16 • Weather conditions; and
- 17 • The need to minimize the substantial costs associated with helicopter flight time.

18
19 The baiting regime would follow common practice based on successful island rodent
20 eradications elsewhere in the U.S. and globally (Howald et al. 2007a), in which overlapping
21 flight swaths are flown across the interior island area and overlapping swaths with a deflector
22 attached to the hopper (to prevent bait spread into the marine environment) flown around the
23 coastal perimeter. The width of a flight swath would be determined beforehand in calibration
24 trials. It would likely range from 164-246 ft (30-80 m). Each flight swath would overlap the
25 previous by approximately 25-50 percent to ensure no gaps in bait coverage. During one
26 application all points on the targeted island would likely be subject to two helicopter passes.
27 Within each bait application, there would likely be no more than three consecutive operating
28 days.

29
30 In order to ensure eradication success, it will likely be necessary to conduct more than one
31 application, each between **5 and 21 days apart**, to minimize the likelihood of either
32 competitively inferior adult mice or juveniles surviving the initial broadcast because they were
33 not given an opportunity to feed on bait. Nevertheless, if project leaders determine that palatable
34 bait would be likely to remain available for mouse consumption for longer than 10 days after an
35 initial application, a second or third application may not be necessary.

36
37 Bait would be applied strictly according to the limitations set by the EPA's pesticide regulations
38 (FIFRA). The precise bait application rate would not exceed the rate set by the EPA (27kg/ha),
39 with applications occurring at up to 18 kg/ha during the first application and up to 9kg/ha during
40 the second application.

41
42 Bait uptake (including both consumption and breakdown) on the South Farallones in this
43 alternative will be similar to that described in Alternative B. Soon after application, bait pellets
44 would be consumed or cached by mice. Some bait may be consumed by other animals as well,
45 including gulls, but far less mortality would be expected due to the more extensive use of hazing
46 during this alternative. Bait pellets would soon degrade over time and exposure to rain. Pellets

Comment [DG86]: Cite standards

2. Alternatives

1 exposed to heavy moisture would degrade faster than pellets that fall in more protected locations.
2 The application rate will be calculated so that an adequate amount of bait is available for
3 consumption by mice for a period of at least four days.
4

5 As a result of the need for caution near the marine environment, the coastlines of the main
6 islands and offshore islets, which are potential mouse habitat, may not receive the optimal bait
7 coverage with helicopter broadcast alone. In cases where it is evident or suspected that any land
8 area did not receive full coverage, there would be supplemental systematic broadcast either by
9 foot, boat, helicopter, or any combination of the above. Helicopters may hover for brief periods
10 over land during bait application to bait offshore islets, either by hand or from the hopper with
11 the broadcast motor off to trickle bait at a precise point directly underneath.
12

13 Areas within the aerial broadcast exclusion zones would be hand baited or baited with bait
14 stations. These areas include the houses, outbuildings, water catchment, and some highly
15 invaginated shoreline areas and cliffs to minimize drift into the marine environment.
16

17 Bait stations would be installed in and immediately surrounding all of the buildings and enclosed
18 structures on the island, as well as in the southwestern portion of Southeast Farallone. The bait
19 used in bait stations would be identical to the bait pellets used for broadcast. The bait stations
20 would have the design specifications listed in Section 2.4.4. A limited number of bait stations
21 could also be installed elsewhere on the island as necessary.
22

23 All personnel that handle bait or monitor bait application in the field would meet or exceed all
24 requirements for personal protective equipment (PPE) required by the EPA. All personnel who
25 may participate in supplemental hand broadcasts would be trained and tested in systematic bait
26 application at a target application rate (Buckelew et al. 2005a). All bait application activities
27 (aerial broadcast, hand broadcast, and bait station filling) would be conducted by or under the
28 supervision of pesticide applicators licensed by the State of California.
29

30 **2.6.6. Project Support Operations**

31 In addition to applying bait, helicopters would be used to transport equipment and personnel to
32 the island for the purpose of this action. These additional helicopter operations would be
33 localized to discrete flight paths that would be determined so as to minimize disturbance to
34 native wildlife. Helicopters may hover for brief periods over land to drop off personnel and
35 equipment.
36
37

38 Helicopters may be staged from the island, mainland or from a boat offshore of the island.
39 Helicopters would only land at designated staging areas, where staff would re-fill the bait
40 hopper, re-fuel, and conduct other necessary maintenance. These staging areas would be
41 adequately stocked with fuel and other supplies and equipment to support the helicopter for the
42 entire bait application process.
43
44

45 **2.6.7. Mitigation Measures**

46

Comment [DG87]: Cite standards for deciding where and when and how much to apply

2. Alternatives

1 All of the mitigation measures proposed to be used in the other action alternatives will be
2 employed in this alternative as well, and have been described in Section 2.2, Features Common
3 to All Alternatives. The mitigation features unique to this alternative include the extensive and
4 intensive hazing of the gulls and the phasing of the baiting operation to allow both the gulls and
5 the pinnipeds an undisturbed site to roost and haul out while the other island is being baited.

Mortality reduction methods to be employed for this and all action alternatives would include:

- **Timing:** Conducting the operation at a time of year when the resident seabird, shoerbird and land bird populations are at their lowest.
- **Carcass removal:** Dead mice, birds or any other animal found that is suspected of having succumbed to the toxicant, will be removed when found to reduce the likelihood of secondary exposure in scavengers;
- **Burrowing owl capture and relocation:** Efforts will be made to capture the transient burrowing owls arriving on island and to hold and release them on the mainland, as the Service has done in the past, to reduce the risk of toxicant exposure; and
- **Capture, hold and release efforts for other resident and migrating raptors:** The resident pair of Peregrine falcons and Common ravens (*Corvus corax*), and possibly other migrating raptors may be captured and removed until the Service determines the birds would no longer be at risk of exposure to toxicant;
- **Use of bait stations:** In areas with particularly high concentrations of roosting gulls to reduce gull uptake of bait.
- **Unique to this alternative: Intensive gull hazing efforts** will be employed to reduce gull pellet and mouse consumption and other non-target mortalities by utilizing extensive bird techniques developed and tested during a January 2011 hazing trial. Techniques tested may include lasers, air canons, poppers, screamers, trained dogs, kites, distress calls, flares, and remotely operated aerial toys.

Comment [DG88]: Add and refer to hazing plan

Pinniped disturbance reduction methods used for this alternative:

- **Timing:** Conducting the operation and before and after the pinniped pupping seasons;
- **Crouching** or crawling when necessary to remain out of view of nearby animals;
- **Moving slowly** and deliberately to avoid frightening animals while traveling by foot
- **Avoiding sensitive areas** when possible to reduce disturbance to haul-out sites
- **Education and Training:** All staff would be shown maps detailing areas with sensitive wildlife and trained on how to avoid disturbing wildlife and avoiding impacts to sensitive habitats such as nesting burrows and crevices.
- **Unique Element: Phasing of baiting/hazing** to allow pinnipeds a safe haul out refuge.

41 **Addition mitigation:** Alternative D will also employ the use of a controlled surveillance flight
42 with a PRBO marine biologist prior to any aerial bait applications. Although none will likely be
43 breeding during the aerial application window, pinnipeds will likely still be present in potentially
44 large numbers during the late fall and early winter. In order to reduce the risk of unpredictable
45 and potentially harmful disturbance to pinnipeds from helicopter operations, the helicopter pilot
46 would conduct a controlled surveillance flight around the coastline before bait operations begin

2. Alternatives

1 in which pinniped haulout locations are noted. During this surveillance flight, an experienced
2 pilot would approach major haulout sites with the intention of exposing hauled out animals to a
3 gradual auditory and visual disturbance similar to the bait application. This controlled “dry run”
4 would likely enable the animals to become aware of the helicopter and then move off of major
5 haulouts into the water, which would allow the helicopter to treat coastal areas immediately
6 afterward while most pinnipeds are still in the water rather than hauled out again. This approach
7 would reduce the risk of a stampede among hauled out animals, thus reducing their risk of injury.
8 This technique was successfully employed in both the Anacapa Island treatment and the Rat
9 Island treatment in the USFWS Alaska Maritime Wildlife Refuge (Citation).

Comment [DG89]: Add citation proper

2.8. Comparative Summary of Actions by Alternative

Table 2.1. Comparison of important attributes of actions under each action alternative.

Action attribute	Alternative B	Alternative C	Alternative D
Primary bait delivery method	Aerial broadcast	Bait stations	Phased aerial broadcast
Secondary bait delivery methods	Hand broadcast Bait stations	Aerial broadcast Hand broadcast	Hand broadcast Bait stations
% of land area with aerially broadcast bait	~95%	65-70%?	~95%?
Start season	Late fall	Early fall	Late fall
Duration	~1 month	Up to 2 years	~ 1.5 months
Chance of success	Good	Moderate-low	Moderate-good
Risk to non-targets	Moderate (gulls)	Lower	Lowest
Amount of disturbance to sensitive breeding birds and mammals	Low	High	Low

2.9 Alternatives Dismissed from Detailed Analysis

2.9.1 Use of a First-Generation Anticoagulant (Diphacinone)

14 The rodenticide brodifacoum, which is classified as a “second-generation” anticoagulant, has
15 been used in 71 percent of documented successful rodent eradication operations (Howald et al.
16 2007a). However, due to the potency of brodifacoum, there is interest in the conservation
17 community for the examination of less-toxic alternative compounds for rodent eradication
18 purposes. Diphacinone, a “first-generation” anticoagulant, is the most commonly considered
19 alternative compound because it has been used for localized rodent control for conservation
20 purposes (VanderWerf 2001, Nelson et al. 2002). However, diphacinone has been used only
21 rarely on islands to eradicate rats (Wingate 1985, Donlan et al. 2003, Witmer 2007). Land
22 managers in Hawai'i recently completed two aerial broadcasts of diphacinone to eradicate rats
23 from small offshore islands; Mokapu was a success and Lehua was a failure. Other diphacinone-
24 based island rodent eradications have been conducted with bait stations. Additionally,
25 diphacinone has never been successfully used to eradicate mice (Howald et al. 2007a).

2. Alternatives

1
2 The toxicity of diphacinone to mice is unclear; rats are considered to be fairly sensitive to
3 diphacinone, but experiments have shown a wide range of sensitivity for house mice from
4 relatively low to very high (Erickson and Urban 2004a). Furthermore, due to the weaker
5 physiological binding properties of diphacinone, rodents have to feed on diphacinone bait in a
6 very large quantity and often multiple times over a period of several days in order to achieve
7 mortality. By comparison both rats and mice are very susceptible to brodifacoum, which can
8 result in high mortality rates after only a single dose. While there are differences in toxicity
9 among taxa, relative potency is better illustrated by comparing the amount of rodenticide bait
10 that must be eaten in order to reach a roughly 50 percent probability of mortality, known as an
11 LD₅₀ dose. According to scientific evidence, house mice would need to eat at least 60 percent of
12 their body weight for up to five days in order to achieve an LD₅₀ dose of 50 ppm diphacinone. In
13 comparison, house mice would need to eat only between one percent and 2.6 percent of their
14 bodyweight in a single dose to achieve the same level of mortality with 20 ppm brodifacoum
15 (Fisher 2005).

16
17 In experimental trials with wild-caught house mice, diphacinone pellets did not kill any of the
18 mice after three days of exposure in a captive laboratory situation (Witmer 2007). After seven
19 days of exposure, diphacinone pellets still only killed 40 percent of the treatment mice. By
20 comparison, brodifacoum pellets resulted in 80 percent and 100 percent efficacy (two different
21 brodifacoum baits were tested) after three days of exposure.

22
23 The risk of failing to eradicate mice using diphacinone is very high for the following reasons: 1)
24 the low toxic threshold of diphacinone to mice, 2) the large amount of bait that mice would need
25 to eat to achieve that threshold, and 3) the typically sporadic feeding habits of mice (Rowe
26 1973), which would reduce the probability that mice would feed consistently on the bait. For
27 these reasons, the use of diphacinone as an alternative bait has been dismissed in this evaluation.

2.9.2 Use of Other Toxicants

28
29
30
31
32 The use of other rodenticides registered with the EPA was dismissed from further consideration,
33 for one or more of the following reasons; 1) lack of proven effectiveness in island mouse
34 eradications; 2) potential for development of bait shyness in the mouse population; and 3) the
35 lack of an effective antidote in case of human exposure. Each of these issues and the associated
36 rodenticides are discussed below.

37
38 The vast majority of documented island-wide rodent eradication programs (226) have used
39 brodifacoum or similar “second-generation” anticoagulants, while only 29 have used “first-
40 generation” anticoagulants such as diphacinone (Howald et al. 2007a). Nine additional
41 eradications have used non-anticoagulant toxicants including zinc phosphide, strychnine, and
42 cholecalciferol. Acute rodenticides, such as zinc phosphide and strychnine, have the ability to
43 kill mice quickly after a single feeding. However, because poisoning symptoms appear rapidly,
44 the acute rodenticides can induce future bait avoidance if animals consume a sub-lethal dose.
45 Studies of zinc phosphide have demonstrated that rodents associate toxic symptoms with bait
46 they had consumed earlier if the onset of symptoms occurs within 6 to 7 hours after consumption

2. Alternatives

1 (see Lund 1988). Thus, any individual that consumes a sub-lethal dose is likely to avoid the bait
2 in the future (Record and Marsh 1988). Also, acute rodenticides are often extremely toxic to
3 humans and there are not always effective antidotes. The combination of these factors
4 disqualifies the acute rodenticides from detailed consideration.

5
6 Cholecalciferol, which is classified as a “subacute” rodenticide, has the ability to kill mice more
7 quickly than the anticoagulant rodenticides, but most often more slowly than the acute
8 rodenticides. Cholecalciferol has a lower level of toxicity to birds. It has been used successfully
9 to eradicate rats from very small islands (Donlan et al. 2003). While these characteristics show
10 potential as a candidate toxicant for eradications, the effectiveness of cholecalciferol in
11 eradicating mice has not been tested. Furthermore, in experimental trials with wild-caught house
12 mice, oral cholecalciferol killed only 20 percent of treatment mice after 3 days of exposure in a
13 captive laboratory situation (Witmer 2007). After 7 days of exposure, cholecalciferol was still
14 only 20 percent lethal. Cholecalciferol’s dubious efficacy for mice disqualifies it from detailed
15 consideration.

16
17 Diphacinone was also considered but rejected due to the comparative likelihood of completing a
18 successful eradication using this bait product. It is critical to recognize that the differences in
19 toxicity and palatability between these brodifacoum and diphacinone products that results in
20 different likelihoods of successful rat eradication.

21
22 At a basic level, from the perspective of operational efficacy, brodifacoum is a better choice for
23 rat eradication than diphacinone because the higher toxicity and efficacy of brodifacoum means
24 there is a greater probability of eradication success. In addition, a greater efficacy is more
25 important for bait broadcast delivery than for bait station delivery where bait can be made
26 available for long periods of time. A rat eradication using brodifacoum has been proven to be
27 successful using either one or 2 aerial bait applications. For diphacinone, the few successful
28 eradications using aerial application means that a strategy for aerial application has not been
29 extensively tested. Given the knowledge that diphacinone is physiologically more effective at
30 low repeated doses, and that successful eradications using bait stations have required
31 diphacinone bait to be consistently available for long periods, aerial application of diphacinone
32 would require multiple applications.

33
34 As such, a brodifacoum eradication using aerial techniques would be more cost-efficient and
35 more effort-efficient than a diphacinone broadcast, which might demand at least 4 broadcast
36 applications over a period of 30 days or more in order to make bait consistently available for the
37 required period. The higher toxicity of brodifacoum also renders the eradication at less risk of
38 failure. Diphacinone, delivered by aerial broadcast, has successfully eradicated rats from 3
39 islands and failed on one (see Table 2). The multiple-feed requirement of diphacinone as a
40 contributor to operational failure for aerial applications cannot be ruled out. On Lehua Island,
41 Hawai`i, where aerial broadcast of diphacinone in 2009 was unsuccessful at eradicating rats,
42 island managers believed that the success of the operation was compromised by unanticipated
43 regulatory actions that prevented implementers from conducting more than 2 broadcast
44 applications, as well as limited bait broadcast around the coastline. In comparison, brodifacoum,
45 delivered by aerial-broadcast, hand-broadcast, or a combination of both, has been used
46 successfully for rodent eradication on at least 75 occasions (Howald et al. 2007b).

2. Alternatives

1
2 In comparison to broadcast delivery, bait station delivery allows implementers to deliver bait into
3 every potential rat territory, over a longer period of time, and with more opportunity to adapt to
4 the changing dynamics of a decreasing rat population. However, effective bait station delivery
5 requires the majority of the rat population on the island to enter a bait station to consume bait, a
6 behavioral requirement that leaves the operation potentially vulnerable to failure if some rats are
7 hesitant to enter stations. While this behavioral requirement can compromise the success of rat
8 eradication regardless of the toxicant used, it is a greater risk when using diphacinone because of
9 the multiple-feeding requirement; rats would need to enter bait stations repeatedly on multiple
10 consecutive days. However, diphacinone delivered in bait stations has been used to successfully
11 eradicate rats from at least 10 islands (Table 2). In comparison, brodifacoum delivered in bait
12 stations has been used successfully to eradicate rats from islands on at least 92 occasions
13 (Howald et al. 2007b) (Island Conservation unpubl. data).

14
15 Bait palatability is another important aspect of the likelihood of successful rat eradication. The
16 products Brodifacoum-25D™ and Ramik® Green (comparable to Diphacinone-50™) have both
17 been shown to be preferred by most rats over locally available natural food sources.
18 Brodifacoum-25 bait products (Bell Laboratories, Madison, WI) have been used to successfully
19 eradicate rats on at least 5 islands, and have shown favorable results in at least 3 other
20 eradication trials. The bait product Diphacinone-50™ has not yet been proven to successfully
21 eradicate rats, but a comparable product (Ramik® Green) was successfully used on Mokapu
22 Island, Hawaii. Ramik® Green has also shown at least partially favorable results in trials the
23 Aleutian Islands. Both of these products appear to provide adequate palatability for the purpose
24 of rat eradication.

25
26 While bait product choice is an important component of eradication efficacy, the most important
27 component is the methodology used for bait delivery. Bait delivery methodology can vary
28 significantly due to the specific bait product used, the equipment and supplies available for
29 implementation and, most importantly, characteristics of the local environment. There is no
30 single “recipe” for successful rat eradication beyond the basic principle of ensuring that every rat
31 on the island is exposed to a lethal dose, which varies by species and toxicant. Implementers
32 must approach each new project with a strategy that is customized for the parameters of the
33 project. This being said, implementers can and should adopt and adapt strategies from other
34 successful eradications. For Palmyra Atoll, the proven record of successful eradications using
35 aerially-broadcast brodifacoum – at least 58 operations – provides a comprehensive set of tested
36 methodologies from which to design a strategy.

37
38 From an operational perspective, the essential difference between application of diphacinone-
39 50™ and brodifacoum-25D™ to eradicate mice from the Farallones would be that quantities of
40 diphacinone need to remain relatively consistent across a period of up to 12 days. With a
41 brodifacoum operation, a mouse that ingests bait on day one will likely not need to ingest bait
42 again because brodifacoum has a high binding affinity and is metabolized slowly. However, with
43 a diphacinone operation, bait needs to be available to all mice for 10-12 days; this requires that
44 (a) the bait is highly attractive to rats, to ensure that rodents prefer it above natural food items, (b)
45 that sufficient bait is available daily to ensure mice frequently encounter bait within their
46 environment, (c) that the consistent bait uptake in the environment through ingestion by mice,

Comment [DG90]: Citation? Get from GH

2. Alternatives

1 and other animals, and degradation by invertebrate, microbial, and other environmental action
2 does not diminish the amount of bait available to the level at which sufficient bait is no longer
3 daily available for ingestion by mice.

4
5 Conservation practitioners seek to avoid causing harm to biological resources. However, affect to
6 individual animals or plants that are incidental to a conservation action can arise. FWS policy,
7 and other government regulations, acknowledge that circumstances exist in which the
8 responsible management of Refuge lands may necessitate actions that might incidentally harm
9 individual animals or plants. For example, a recent clarification of the Migratory Bird Treaty Act
10 (MBTA) (FWS 2010) has allowed for the issuance of a special-purpose permit during invasive
11 species eradication actions where *take* of listed migratory birds is possible when the overall
12 effects to migratory birds is positive. Therefore, potential incidental harm to individual animals
13 during mouse eradication operations on the Farallones may be acceptable as long as any
14 individual impacts are outweighed by the expected beneficial effects of mouse eradication to the
15 ecosystem.

16
17 In conclusion, from the perspective of the likelihood of eradication success, Brodifacoum-25D™
18 is a better choice than Diphacinone-50™, due to its higher toxicity and extensive proven record.
19 While use of diphacinone imparts a considerably lower risk to non-target species than
20 brodifacoum, the difference in the predicted likelihood of success of Brodifacoum-25D™ in
21 comparison to Diphacinone-50™ is an important consideration when deciding between the
22 alternatives rodenticides available. The concern for potential non-target impacts, especially non-
23 target impacts that would not affect species at a population level are important, but the need to
24 ensure eradication success is critical. A failed eradication attempt would provide no conservation
25 returns in the long term, since mice would quickly re-establish throughout the island (Buckelew
26 et al. 2005b). The most cost-effective conservation returns on ~~rat~~ eradication investment is
27 through a successful eradication on the first attempt.

Comment [DG91]: Add additional info from RI

2.9.3 Use of Disease

31
32 While there is ongoing research focused on the development of taxon-specific diseases that can
33 control populations of non-native species (such as by the Australian agency CSIRO,
34 www.cse.csiro.au/research/rodents/publications.htm), there are no pathogens with proven
35 efficacy at eradicating rodents (Howald et al. 2007a). Even a highly lethal mouse-specific
36 pathogen would be ineffective at eradicating mice from the South Farallones, because the mouse
37 population would most likely rapidly declined, causing the introduced disease to disappear
38 before fully infecting the entire mouse population. Furthermore, the introduction of novel
39 diseases into the environment carries tremendous unknown risks to non-target species.

2.9.4 Trapping

41
42 This alternative would call for the use of live traps and/or lethal (“snap”) traps to eradicate mice.
43
44 This action is highly unlikely to succeed on the South Farallones. The use of live traps and/or
45 lethal traps to remove mice from an area is a strong selection agent in favor of mice that are
46

2. Alternatives

1 “trap-shy”. Thus, after extensive trapping the only mice that would remain would be those that
2 are behaviorally less likely to enter a trap, and these mice will be very difficult to remove
3 without the introduction of alternate methods such as toxicants. Furthermore, the widespread use
4 of traps is not feasible because of the extensive effort and considerable personnel risk required to
5 set and monitor traps. Therefore, this alternative would not be feasible to implement.
6
7

8 **2.9.5 Biological Control**

10 The alternative to introduce predators on mice, such as snakes and cats, was dismissed because
11 biological control most often only reduces, rather than fully eliminates the target species failing
12 to achieve the desired ecological benefit gained through complete mouse removal. There is no
13 known effective biological control agent for mice on islands, and some forms of biological
14 control would result in unreasonable damage to the environment. The introduction of cats to
15 islands in order to control introduced rodents has been attempted numerous times since European
16 explorers began crossing the Atlantic and Pacific Oceans. The introduction of a rodent predator,
17 such as cats, generally results in a greater combined impact on birds than if one or the other were
18 present alone. When seabirds are present, cats have been shown to prey heavily on seabirds
19 (Atkinson 1985), consuming fewer rodents during these times. When seabirds migrate off of the
20 islands following the breeding season, cats switch prey to rodents, which allows the island cat
21 population to remain stable at higher levels than if no rodents were present on the island
22 (Atkinson 1985, Courchamp et al. 1999, 2000). Thus, birds are impacted not only by rodents but
23 the larger number of cats that are sustained by rodent presence on the island. Introducing another
24 species onto an island can have severe and permanent consequences to the ecosystem (see
25 Quammen 1996). Therefore, this alternative was eliminated from further consideration.
26
27

28 **2.9.6 Fertility Control**

30 Fertility control has been used with limited success as a method of pest management for a few
31 invasive species. Experimental sterilization methods have included chemicals and proteins
32 delivered by vaccine, and genetically-modified viral pathogens. However, the effectiveness of
33 these experimental techniques in the wild, as well as their impacts to non-target animals, are
34 unknown. Aerial application of rodenticide is a more practical, effective, and safer method to
35 eradicate mice than repeated baiting of oral contraceptives on a remote island across seasons or
36 capturing, vaccinating, and releasing every member of one gender of the South Farallones’
37 mouse population. This lack of data and tools disqualifies the use of fertility control from
38 detailed consideration (Tobin and Fall 2005).
39
40

41 **2.9.7 Mouse Removal with the Goal of “Control”**

43 The net conservation gain achieved by mouse control (i.e. reducing and maintaining mouse
44 populations at extremely low levels), rather than complete eradication, is comparatively small,
45 yet the risks to non-target wildlife are nearly doubled from the combined impacts from mice and
46 control operations. Mice can reproduce rapidly and re-colonize areas from which they were

2. Alternatives

1 previously eliminated. The constant maintenance of an ecologically beneficial mouse control
2 program (i.e. control of mouse populations to levels low enough island-wide to eliminate them as
3 a reliable food source for migrating burrowing owls) is far less cost-effective and does not result
4 in the permanent conservation benefits of entire-island eradication, and was therefore eliminated
5 from consideration.
6
7

ADMINISTRATIVE REVIEW DRAFT

Chapter 3: Affected Environment

3.1. Introduction

The Farallon National Wildlife Refuge was established in 1909, and expanded to its current size in 1969. It includes all of the islands in the Farallon group. Within the Refuge, all of the emergent land except the island of Southeast Farallon is Designated Wilderness under the Wilderness Act of 1964. The Service has cooperative agreements with PRBO Conservation Science and the U.S. Coast Guard to facilitate protection and management of the Refuge.

The waters around the Farallones below the mean high tide line are part of the Gulf of the Farallones National Marine Sanctuary. This Sanctuary is one of three contiguous Marine Sanctuaries, with Cordell Bank National Marine Sanctuary to the north and Monterey Bay National Marine Sanctuary to the south, which together convey special protected status to the biological resources of almost 7,000 square miles of ocean from Cambria to Bodega Bay and out to sea well past the continental shelf.

The Farallones' isolated nature, varied and extensive habitats, and adjacent productive marine environment makes them an ideal breeding and resting location for wildlife, especially seabirds and marine mammals. The Refuge comprises the largest continental U.S. seabird breeding colony south of Alaska, and supports the world's largest breeding colonies of ashly storm-petrel, Brandt's cormorant (*Phalacrocorax penicillatus*), and western gull.

The Farallones have also had extensive human activity beginning in the early 1800s when marine mammals were harvested for fur and food, as an egg gathering venture in the mid to late 1800s, a military outpost during two world wars, and until 1972 as a manned U.S. Coast Guard light station. ~~Wildlife populations were heavily exploited from the late 18th to late 19th centuries for meat, hides, and eggs.~~ Over-fishing of Pacific sardines (*Sardinops sagax*) in the mid-20th century may have reduced seabird and marine mammal food supplies. ~~Some species were extirpated or declined drastically.~~ The active U.S. Coast Guard station further impacted island wildlife and habitat until the full automation of the light station in 1972. Under FWS stewardship, some extirpated species have re-colonized the islands, and wildlife populations as a whole are slowly recovering. Still, certain Refuge species remain at reduced population levels or are even declining, and wildlife remains vulnerable to the impacts of introduced animals and plants, oil spills, other pollution, fisheries interactions, and global climate change.

3.2. General Description of the South Farallon Islands

3.2.1. Geographical Setting

The South Farallon Islands are situated just inshore of the continental shelf edge, 28 miles west of the Golden Gate and the city of San Francisco, California, at 37°42'N latitude and 123°00'W longitude. The South Farallones are made up of two main islands that are separated by a narrow channel: Southeast Farallon Island and West End (or "Maintop Island"). Several offshore islets

3. Affected Environment

1 immediately surround the main islands, including Saddle (or “Seal”) Rock, Sugarloaf, Arch
2 Rock, Aulon Islet, Sea Lion Rock and Chocolate Chip.

3
4 The Farallon Island group and the Farallon National Wildlife Refuge also includes a number of
5 islets that extend to the northwest, including the North Farallon Islands, Middle Farallon, and
6 Noonday Rock, which becomes completely submerged at times. These islets to the northwest are
7 isolated, relatively small, barren, extremely difficult to access, and are not known to harbor
8 house mice or any other non-native mammals. Thus, they would not be included in the mouse
9 eradication actions described and analyzed in this document.

Comment [g92]: We need to confirm this!

Comment [g93]: Is this still true?

3.2.2. Size and Topography

10
11
12
13
14 The South Farallones have a planar land area of approximately 120 acres (49 ha). The highest
15 peak, at the top of Lighthouse Hill, is 370 ft (113 m) above sea level. The topography is
16 generally rocky and uneven, with comparatively flat terraces at the lower elevations of Southeast
17 Farallon. The coastline is generally steep, rocky, wave-washed, and difficult to access. The south
18 side of Southeast Farallon has an extensive marine terrace that terminates into an large intertidal
19 zone. West End is dominated by the steep-sided, dome-shaped peak called Maintop, and several
20 other smaller peaks and ridges. An extensive north-south valley, called Shell Beach, is situated
21 on the western side. See Appendix A for a topographic map of the South Farallon Islands.

3.2.3. Climate

Comment [g94]: Input weather table for at least the last five years! Contact Tom at NOAA

22
23
24
25
26 The climate of the Farallones is characterized by moderate temperatures, wet winters and dry
27 summers. The average temperature is 55.2 °F (12.9 °C) with little seasonal variation. September
28 is the hottest month (average temperature 59 °F (15.0 °C)), and January the coldest (average
29 temperature 52.3 °F (11.3 °C)). The region's hottest days are typically during the fall when high
30 pressure builds into the Pacific Northwest and Great Basin, and dry offshore winds replace the
31 Pacific seabreeze. The three hottest days on record in the city of San Francisco occurred in
32 September and October (Null 1995). The lowest and highest temperatures recorded for Southeast
33 Farallon Island from 1971 through 2007 were 34 °F (1.1 °C) in December 1990, and 90 °F (27.2
34 °C) in September 2000.

35
36 Summertime is characterized by cool marine air with persistent coastal stratus and fog. Rainfall
37 from May through October is relatively rare. Considerable moisture, although rarely measurable
38 as precipitation, is due to drizzle when the marine layer deepens sufficiently. Spring and fall are
39 transition periods. Spring and early summer are characterized by strong northwesterly winds.
40 The occurrence of rainfall during the early spring and fall is infrequent. While most storms
41 during these periods produce light precipitation, there are occasional heavy rainfall events. In
42 winter, the islands experience periods of storminess and moderate to strong winds, as well as
43 periods of stagnation with very light winds. Annual rainfall averages 20 in (with a standard
44 deviation of 7.25 in). Winter rains (November through April) account for about 89 percent of the
45 average annual rainfall.

3. Affected Environment

1 Climate data summarized here are from PRBO unpublished data 1971-2007 except where noted
2 otherwise.

3.3. Physical Resources

3.3.1. Water Resources

3
4
5
6
7
8
9 Since 1998 a rainwater collection, filtration, and distribution system has supplied all of the field
10 station's water needs. Water samples are tested three to four times a year ~~by Alameda County~~
11 ~~Water District~~ for coliforms and nitrates. Results have largely been below levels of concern, and
12 any water quality issues have been quickly resolved.

13
14 Marine water quality within the surrounding Gulf of the Farallones National Marine Sanctuary
15 (NMS) is somewhat unaffected by threats to water quality due to the distance from sources of
16 pollutants and land-based runoff, as well as the continuous circulation of the offshore waters at
17 many scales. However, discharges from sunken vessels and illegal discharges from oil tankers
18 and cargo vessels have been a periodic source of negative impacts to marine organisms within
19 the sanctuary. The threat of an offshore spill is a constant presence in areas near well-used
20 shipping lanes. In the event of an oil spill, the impact to the open coast would mainly be
21 determined by the wind and sea conditions, which could easily overcome protection efforts.
22 Also, persistent organic pollutants such as DDT and PCBs were widely used nationwide before
23 the mid-1970s, and residuals of these chemicals still remain in sediments and organisms within
24 the Sanctuary. Elevated levels of pollutants have been reported for fish, seabirds, and marine
25 mammals found within the Sanctuary (NOAA 2008).

26
27 The waters surrounding the South Farallones have also been designated as an Area of Special
28 Biological Significance (ASBS). California regulations prohibit any waste discharge into ASBSs.
29 A recently-installed septic system on Southeast Farallon treats all wastewater generated by the
30 field station, and disperses it into a leach field located a sufficient distance away from the ocean
31 to avoid pollution of the surrounding waters and to ensure compliance with California marine
32 water quality regulations.

Comment [g95]: Check on this status!

33
34 Between 1946 and 1970, nearly 50,000 drums of hazardous and radioactive wastes were dumped
35 over a 350 square nautical mile area overlapping the boundaries of the Gulf of the Farallones
36 NMS. Unfortunately, the precise locations of these drums are unknown, and only 15 percent of
37 the potentially contaminated area has been mapped. The extent of contamination to the waters
38 surrounding the islands is unknown (Karl et al. 2001).

3.3.2. Geology and Soils

39
40
41 The Farallones are composed primarily of granitic rock, which is evidence of the ancient marine
42 terraces that they are a part of. During the last ice age, the coastline of California extended
43 beyond the Farallones, and the islands were part of a coastal range of hills that is now almost
44 entirely submerged. The Refuge is primarily made up of rocky surfaces with little soil coverage.
45
46

3. Affected Environment

1 However, much of the marine terrace and certain other portions of Southeast Island are covered
2 with dark brown soil up to eight inches thick (Vennum et al. 1994). Soil examination indicates
3 that the composition is largely made up of decomposing guano and granitic sand and lesser
4 amounts of feathers, bone fragments, vegetation, possible fish teeth and human-made detritus
5 (Vennum et al. 1994).

3.3.3. Wilderness Character

6
7
8
9
10 West End Island is Designated Wilderness as regulated by the Wilderness Act (PL 88-577). See
11 Appendix B for a map illustrating the Farallon Wilderness. Under the Wilderness Act, an area's
12 wilderness character is defined by the following qualities:

- 13 1. Untrammelled by human impacts;
- 14 2. Undeveloped, without permanent structures or habitations;
- 15 3. Influenced primarily by natural forces; and
- 16 4. "Has outstanding opportunities for solitude or a primitive and unconfined type of
17 recreation."

18
19 The overall goal of wilderness management under the Wilderness Act is to keep lands as wild
20 and natural as possible, including restoring the wilderness character where it has been severely
21 damaged by human use or influence. Because one of the major components of wilderness
22 character is that it be untrammelled by human activities, one of the most important stipulations of
23 the Wilderness Act is that all necessary wilderness management work be conducted with the
24 "minimum tool" required for the job. The "minimum tool" has the least discernible impact on the
25 land and is the least manipulative or restrictive in achieving a management objective. Under this
26 principle, the use of vehicles, motorized tools, and other mechanized devices are generally
27 discouraged, but in some instances the use of mechanized tools or equipment are necessary for
28 the action agency to effectively manage designated wilderness areas. The Wilderness Act and
29 other related agency-specific guidance provides a general framework for determining the
30 minimum tool necessary to complete a restoration action in a wilderness area. See Appendix K
31 for a detailed "Minimum Requirements Analysis" for non-native house mouse eradication on the
32 South Farallones.

3.4. Biological Resources

3.4.1. Introduction

33
34
35
36
37
38
39 All of the alternatives described and analyzed in this document, including the alternative of No
40 Action, have the potential to affect the biological resources of the South Farallones. The no
41 action alternative would allow the direct and indirect impacts that non-native house mice
42 currently have on the native species of the South Farallones to continue. The proposed mouse
43 eradication would have three basic types of impacts to biological resources: impacts from the use
44 of rodenticide, impacts from disturbance caused by the personnel activities and machinery
45 operation necessary for bait application, and the subsequent ecosystem response to the removal
46 of mice from the ecosystem. This section will describe the status, trend, and biology of animals

3. Affected Environment

1 and plants on the Farallones as they relate to the potential for each of the alternatives to have an
2 effect on these resources.

3.4.2. Birds on the South Farallones

3
4
5
6
7 Appendix C contains a full list of birds that regularly breed on the South Farallones. Appendix D
8 contains lists of birds that are likely to visit or reside at the South Farallones at some point during
9 the year, categorized according to their risk profiles (detailed in Chapter 4). Appendix F
10 illustrates common seabird roosting and nesting areas.

3.4.2.1. Breeding birds

11
12
13
14 The South Farallones is the largest seabird breeding colony in the lower 48 U.S. states. ~~Thirteen~~
15 bird species are known to breed regularly on the islands, including ~~12~~ seabirds and one shorebird
16 (black oystercatcher, *Haematopus bachmani*). A number of other birds have occasionally or
17 historically bred on the islands as well. During the peak of the summer breeding season there
18 may be more than ~~250,000~~ breeding birds present. Most habitat types on the Farallones are
19 occupied by breeding seabirds between mid-March and mid-August, but some species continue
20 breeding activities through September, and ashy storm-petrels breed until November.
21 Cormorants and common murres inhabit rocky slopes and cliffs. The marine terrace and slopes
22 of Southeast Farallon are dense with nesting gulls, with lower gull densities in other areas. Even
23 below the surface, rock crevices and burrows house nesting storm-petrels, auklets, guillemots,
24 and puffins.

25
26 The Farallones are the breeding site for about half of the world's population of the ashy storm-
27 petrel, which breed only along the coast of California and northern Baja California, Mexico. The
28 Farallones also host the world's largest colonies of Brandt's cormorant and western gull, as well
29 as one of the southernmost colonies of rhinoceros auklet (*Cerorhinca monocerata*) and tufted
30 puffin (*Fratercula cirrhata*) on the west coast of North America. Common murre, which nest in
31 extremely dense colonies, are the most abundant breeding species ~~and~~ the Farallones ~~and~~ likely
32 ~~house~~ the largest common murre colony ~~outside~~ of Alaska (G. McChesney pers. comm.).

33
34 The onset of breeding activity varies considerably between seabird species. The earliest egg-
35 laying occurs in March with Cassin's auklet (*Ptychoramphus aleuticus*). While most eggs have
36 been laid by early July, some ashy storm-petrels may not lay until as late as August. While the
37 length and dynamics of each species' breeding season differs, there is a clear seasonal pattern
38 among nearly all seabirds in which chicks fledge by no later than September. The only major
39 exception to this are ashy storm-petrels, which primarily fledge in September and October with
40 some chicks fledging as late as December (Ainley 1990, PRBO unpubl. data, Ainley and
41 Boekelheide 1990).

42
43 Many of the seabird species that nest on the Farallones are extremely sensitive to disturbance –
44 they will frighten and take flight readily, and in the process may knock their eggs from their
45 precarious perches or leave them exposed to be eaten by avian predators. Some seabirds will
46 abandon their nest sites for the season if they are disturbed. Disturbance becomes a
47 comparatively smaller concern during the non-breeding season.

3. Affected Environment

1
2 All of the seabirds on the South Farallones can generally be characterized as slow-reproducing.
3 All but one species (Cassin's auklet) raise only one brood annually, and some species lay only a
4 single egg in each clutch. Because they cannot reproduce quickly to counteract negative impacts
5 to their populations, seabirds are especially vulnerable to factors that reduce the survival of
6 breeding adult birds. Small decreases in adult survival can result in population declines and
7 hamper population recovery. As a result, factors that increase mortality in adults can seriously
8 jeopardize seabird populations, especially if population levels are already low (USFWS 2005b).

9
10 A plethora of factors affect each of the seabird species that are present on and around the South
11 Farallones, both at the island and elsewhere in their ranges. The Service's 2005 Seabird
12 Conservation Plan for the Pacific Region describes current threats, management goals and
13 detailed information for seabirds. The most serious human-caused threats to seabirds in the
14 region involve: 1) invasive species; 2) interactions with fisheries (both direct and indirect); 3) oil
15 and other pollution; 4) habitat loss and degradation; 5) disturbance; and 6) global climate change.
16 In addition, all of the species that forage in the waters surrounding the South Farallones are
17 affected by changes in the productivity of the marine ecosystem, which occurs over different
18 spatial and temporal scales. Researchers are often able to find a correlation between years of
19 particularly high or low marine productivity and breeding productivity in the Farallones' seabird
20 species (Ainley and Boekelheide 1990).

21 3.4.2.2. Visiting birds

22
23
24 The productive waters surrounding the Farallones provide foraging grounds for a number of
25 additional species such as grebes, shearwaters, scooters, phalaropes, and several species of gulls;
26 most of which remain in the water or in flight but a few also use the island for roosting.
27 Additionally, the island's intertidal habitat supports a number of shorebird species such as
28 plovers, turnstones, whimbrels, and willets. Finally, many other species of freshwater and
29 estuarine waterbirds have been sighted on the Farallones during migration, and some
30 occasionally overwintered. The community makeup of these additional waterbirds varies
31 substantially, both seasonally and inter-annually.

32
33 There are no permanent resident landbirds on the Farallones, but the island is well known for the
34 number and diversity of landbirds that arrive on the island during spring and fall migrations
35 (DeSante 1983, Pyle and Henderson 1991). More than 400 species of landbirds have been
36 recorded for the Farallon Islands (Richardson et al. 2003, USFWS unpubl. data). DeSante and
37 Ainley (1980) concluded that the vast majority of these arrivals are birds that are in the process
38 of returning to the mainland after veering off their migratory course along California's coast.
39 During the spring and fall large numbers of migrants may be present on the island, often
40 concentrated in and around the small trees that were planted near the residences on Southeast
41 Farallon. While nearly all landbirds spend little time on the islands before departing, perhaps 100
42 or fewer remain through the winter. ~~There are no landbird species that consistently breed on the~~
43 ~~Farallones, although~~ there are occasional historical nesting records for a few species (mainly
44 rock wren *Salpinctes obsoletus*) (DeSante and Ainley 1980).

45 3.4.2.3. Seasonal patterns in the avian communities of the South Farallon Islands

46
47

3. Affected Environment

1 Breeding Seabirds:

2
3 Seabirds that breed on the Farallones also reside on the island during other parts of the year.
4 Western gulls are nearly year-round residents and have peak numbers at the start of the breeding
5 season by mid-March. Adults leave the island at the end of the breeding season in late July and
6 juveniles also leave by mid-September (Pierotti and Annett 1995). However, birds begin
7 returning to the Farallones by early fall to reoccupy territories and numbers increase until they
8 peak again in March (Penniman et al. 1990). Common murrens begin breeding in early May and
9 chicks fledge at only three weeks old in July and August; chicks depart with their fathers to
10 forage in the surrounding waters (Ainley et al. 2002). Most of the breeding population likely
11 remains within a one to two day flight to the breeding grounds, and periodic visits occur in late
12 October or early November. Pigeon guillemot (*Cephus columba*) begin arriving to the
13 Farallones by March, breed beginning in May, and depart from the island soon after chicks
14 fledge; colonies are vacated by early September (Ainley et al. 1990c, Ewins 1993). Cassin's
15 Auklet is the most common seabird present on the Farallones and visits their burrows on the
16 island year round. Depending on the timing of egg laying, Cassin's auklets generally visit their
17 burrows daily between January and June. Visitation decreases substantially in July and continues
18 to decline through December (Ainley et al. 1990b). Rhinoceros auklet and tufted puffin breed
19 on the Farallones, yet this island is the southernmost edge of their ranges in the eastern Pacific.
20 The Farallones consist of 41 and 40% of the California population, respectively. Both species
21 begin arriving to the island for breeding in April and depart by September (Ainley et al. 1990e).
22 Leach's storm-petrels begin arriving at the Farallones at the end of February for breeding and
23 depart by the end of September or mid-October. Ashy storm-petrels are present on the island
24 longer than Leach's and begin visiting in late December. They reach peak numbers in February,
25 and largely depart by mid-November; however, some individuals remain year-round (Ainley et
26 al. 1990d). The most abundant cormorant on the Farallones is Brandt's cormorant; the Farallones
27 house the largest breeding colony of this species world-wide. They arrive for breeding in mid- to
28 late-March, populations peak in late May, and most of the colony departs by August
29 (Boekelheide et al. 1990b). Other cormorant species nesting on the Farallones are Pelagic and
30 double-crested cormorants, although this represents a small portion of their breeding population.
31 Pelagic cormorant arrival ranges from December to April, depending on the weather, although
32 numbers during the winter remain very low. The population peaks in May and June, and most
33 birds depart the island by September (Boekelheide et al. 1990a). Double-crested cormorants
34 generally arrive by April and depart the island by September. Black oystercatchers are present
35 and breeding on the island, although in small numbers (Ainley and Lewis 1974).

36
37 The following section is adapted from DeSante and Ainley's *Avifauna of the South Farallon*
38 *Islands (1980)*:

39
40 The greatest density and diversity of visiting bird species occurs during the fall. Shorebirds,
41 begin arriving in July and gradually increase to maximum visitation rates in September, when the
42 usually rare estuarine and freshwater species also occur.

43
44 Pelagic seabirds (living out in the open sea) occurring offshore of the island reach maximum
45 diversity during September although maximum numbers of sooty shearwater (*Puffinus griseus*)
46 often occur during the summer, and phalaropes are often most abundant in August. With the

3. Affected Environment

1 exception of pelicans and gulls, none of these seabirds land on the islands but rather stay on or
2 above the surrounding waters. The seabirds that breed on the South Farallones are mostly absent
3 from the island during fall.

4
5 Landbird migrants, primarily species breeding in western North America and wintering in the
6 tropics, begin arriving in early August and reach maximum visitation rates in September or early
7 October when the major arrival of landbirds wintering in coastal California occurs. The
8 maximum diversity usually occurs from mid-September to early October. Landbird visitants
9 decline during late October and dwindle to very low numbers by late November.

10
11 Neritic seabirds (deriving nutrients from the region of water lying directly above the sublittoral
12 zone of the sea bottom) begin arriving in very late September or October and reach maximum
13 diversity during November. With the exception of pelicans and gulls, none of these visitant
14 seabirds land on the islands but rather stay on or above the surrounding waters. The fall migrant
15 California brown pelicans (*Pelecanus occidentalis californicus*) are present in maximum
16 numbers in October, often roosting on the islands.

17
18 Besides the ~~year-round resident~~ breeding seabirds, neritic seabirds, particularly eared grebes
19 (*Podiceps nigricollis*), surf scoters (*Melanitta perspicillata*), and large *Larus* gulls frequent the
20 waters around the island during winter. Rocky intertidal shorebirds also winter in low numbers
21 although other shorebirds, including estuarine and freshwater species, while pelagic seabirds are
22 generally very rare. Only a few landbirds winter on the island, including the white-crowned
23 sparrow (*Zonotrichia leucophrys*), the golden-crowned sparrow (*Zonotrichia atricapilla*), the fox
24 sparrow (*Passerella iliaca*), the yellow-rumped warbler (*Dendroica coronata*), the western
25 meadowlark (*Sturnella neglecta*), and the black phoebe (*Sayornis nigricans*). Most overwintering
26 landbirds arrive during the fall migration period, primarily October and November, and depart in
27 March and April. Researchers on Southeast Farallon have recorded a daily average of around 30
28 landbirds and around 60 shorebirds between mid-November and mid-December (PRBO unpubl.
29 data).

30
31 Early spring migrants may first appear in late February but usually arrive in March. Spring
32 migration is generally quite sporadic and unpredictable, especially during March and April. At
33 this time the immense numbers of breeding seabirds begin their nesting activities. Nearly all
34 waterbirds, including most pelagic and neritic seabirds and virtually all estuarine and freshwater
35 species and shorebirds, are rare during the spring migration. However, large numbers of small
36 gulls and phalaropes often pass by the island.

37
38 One and occasionally two major waves of visitant landbirds usually occur in early and/or late
39 May. Different populations are probably involved in each of these flights but most are of species
40 that breed in western North America and winter in the tropics. Very few western landbirds visit
41 after late May or very early June. Spring vagrant landbirds may first appear in mid-May but
42 reach maximum diversity during the first half of June; these include a majority of eastern North
43 American species.

3.4.2.4. Special legal protection for birds on the South Farallones

3. Affected Environment

1 The native birds that visit or reside on the South Farallones are protected from harm by the
2 Migratory Bird Treaty Act (MBTA). Additionally, American Peregrine Falcon (*F.p. anatum*).
3 are federally delisted but still state listed as endangered, and are a “candidate” for state delisting.
4 Peregrines are a migrant, and several (usually between 3 and 5 or so) individuals winter on SEFI.

5
6 No bird species found on the South Farallones are currently listed and either threatened or
7 endangered under the Endangered Species Act.

3.4.3. Terrestrial Wildlife of the South Farallon Islands

3.4.3.1. Seabirds and the South Farallon Islands ecosystem

13 Breeding seabirds are a major component in the terrestrial ecosystem of the South Farallones.
14 Seabirds trample, burrow, and substantially alter the chemical content of the soil through guano
15 deposition across most of the island, which makes the growing environment for plants highly
16 specialized and generally less productive than similar habitat on the mainland. While the effects
17 of seabirds on the island’s soil prevent some species from thriving, they simultaneously provide
18 ideal habitat for many other species. The island’s ubiquitous maritime goldfields, a small
19 herbaceous composite, exists only on seabird breeding colonies and roosts (Vasey 1985). In turn,
20 western gull and cormorants rely heavily on maritime goldfields for nesting material at the South
21 Farallones (Coulter 1971, Ainley and Boekelheide 1990). With increasing seabird populations,
22 the overall use of maritime goldfields by seabirds has also likely increased (PRBO unpubl. data).
23 Similarly, seabird burrows provide habitat for subterranean animals such as the Farallon arboreal
24 salamander and numerous invertebrate species. Finally, the abundance of seabird carcasses that
25 occur on seabird colonies provides a reliable food resource for a host of decomposer
26 invertebrates.

3.4.3.2. Salamanders

30 The arboreal salamander subspecies *Aneides*
31 *lugubris farallonensis* is endemic to the South
32 Farallones. In the most habitat-rich areas of the
33 island, salamander densities can reach nearly
34 300 animals per acre (700/ha) (Boekelheide
35 1975). (Farallon arboreal salamanders are
36 nocturnal insect predators. Like many
37 salamanders, they are lungless, respiring
38 through their skin. While they are most active
39 when the surrounding environment is moist,
40 they are not dependent on water for any part of
41 their lifecycle and are more tolerant of dry
42 conditions than other salamander species
43 (Cohen 1952). They breed and lay eggs during
44 the summer (Boekelheide 1975) with young appearing in the fall (Lee 2008). Salamanders are a
45 major predator of the endemic camel cricket (*Farallonophilus cavernicola*) (Steiner 1989).

Figure 3.1. Arboreal salamander.

3. Affected Environment

1 PRBO Conservation Science recently began collecting baseline data to monitor the seasonal
2 abundance and distribution of salamanders on the South Farallones and ~~thereby measure~~ the
3 impacts of mouse eradication over time (Lee 2008).

Comment [g96]: Do we have any results from these studies yet???

3.4.3.3. Bats

7 There are no breeding or resident bats on the South Farallones. However, a number of bat species
8 are known to visit and roost on the island primarily during fall migration. Most visitors are hoary
9 bats (*Lasiurus cinereus*), but others include western red bat (*Lasiurus blossevillii*), Mexican free-
10 tailed bat (*Tadarida brasiliensis*), little brown bat (*Myotis lucifugus*), and Eurasian pipistrellus
11 (*Pipistrellus* sp.) (~~PRBO unpubl. data~~) (Cryan and Brown 2007).

3.4.3.4. Invertebrates

15 Many of the insects on the South Farallones are most commonly associated with seabird
16 carcasses (Schmieder 1992). This is not surprising given the inevitably high number of carcasses
17 usually found on any seabird colony, including the Farallones. Globally, insects play a major role
18 in processing detritus, and the role of invertebrates in the decomposition of carcasses on the
19 Farallones is particularly critical given the paucity of larger detritivores on the islands compared
20 with ecosystems on the mainland.

Comment [g97]: ***Look up invertebrates; this is very awkward and confusing!!!

22 Few insect studies have been conducted on the Farallones. The most well-described invertebrate
23 endemic to the island is the endemic cave-dwelling camel crickets (~~*Farallonophilus*~~
24 ~~*cavernicola*~~), which is found in caves around the island (Steiner 1989). Surveys for camel
25 crickets would be conducted before and one year after eradication, as standardized surveys for
26 this rare endemic have not been conducted recently. It is expected that the eradication of
27 predatory mice would generally result in increases in the numbers of invertebrates. Additionally,
28 a unique island form of the flightless intertidal beetle (*Endeodes collaris*) has also been described
29 (Giuliani 1982).

3.4.3.5. Non-native animals

33 When the Service incorporated the South Farallon Islands into the Refuge in 1969, there were
34 non-native rabbits, feral cats, and house mice present on the islands. Although island managers
35 do not know when mice were first introduced to the South Farallones, anecdotal evidence
36 suggests that they arrived early in the sequence of human activities, which began in the early
37 1800s. American and Russian sealers, egg collectors, lighthouse keepers, the U.S. Navy and the
38 U.S. Coast Guard all inhabited the island before the Service assumed management and any of
39 these previous occupants could have introduced mice, presumably by accident. Shortly after the
40 Service assumed management of the island they implemented a management program to remove
41 rabbits and cats, which ended successfully in 1975 leaving house mice as the only resident non-
42 native mammal on the Farallones.

44 House mice are small rodents, around 0.5-0.7 oz (15-20 g) in mass. They are prolific breeders,
45 with females commonly producing six to eight litters a year, each with four to seven young
46 which mature within 3 weeks and are reproductively active soon after (Witmer and Jojola 2006).
47 Individual house mice most frequently travel no further than 49-66 ft (15-20 m) from a burrow,

3. Affected Environment

1 although occasional forays of longer distances do occur (Triggs 1991, Ruscoe 2001). House mice
2 are omnivorous; mice on the Farallones eat both vegetation and invertebrates year-round and
3 have been found with eggshell fragments and seabird feathers in their stomachs during the
4 seabird breeding season (it is possible that these seabird remains came from scavenged eggs or
5 carcasses) (Jones and Golightly 2006).

6
7 The population of non-native house mice on the South Farallones is highly cyclical, growing
8 steadily and rapidly throughout the summer to a peak in October and then crashing just as rapidly
9 as food resources decline through the winter to a low in April (Irwin 2006, Jones and Golightly
10 2006). Mice are the primary prey item for burrowing owls during the fall and early winter
11 months. As discussed in Section 1.3.1, the presence of mice as a seasonal food resource for
12 burrowing owls has enabled these owls to subsequently prey heavily on small seabirds such as
13 storm-petrels each spring when mouse numbers are low. The islands' ashy storm-petrel breeding
14 population was reported to have declined more than 40 percent between 1972-73 and 1992
15 (Sydeman et al. 1998). This decline likely resulted, in part, from the presence of mice on the
16 South Farallones.

17
18 While mice are the only non-native mammalian residents on the South Farallones, non-native
19 landbirds such as European starling (*Sturnus vulgaris*), house sparrow (*Passer domesticus*), and
20 rock pigeon (*Columba livia*, commonly known simply as "pigeon") may be present during
21 migration and winter. Starling and house sparrow have also bred on the South Farallones in the
22 past, but have not been reported in the past decade. Non-native birds are unlikely to have any
23 impact on the small avian landbird community of the islands.

26 3.4.4. Intertidal and Nearshore Ecosystems

27
28 This section was compiled with information from J. Roletto (NOAA – Gulf of the Farallones
29 NMS), personal communication.

30
31 Gulf of the Farallones National Marine Sanctuary is contiguous with the Farallon National
32 Wildlife Refuge at the mean-high tide line. The Sanctuary has conducted long-term monitoring
33 of plants and invertebrates in the rocky intertidal habitats of the Farallon Islands since 1992. Data
34 include percent cover, density counts, and species inventories. Surveys are conducted annually
35 during late summer (August), fall (November) and winter (February) months.

36
37 The intertidal habitat between the low and high tides is characterized by extreme conditions
38 caused by wind, waves, and the fluctuation of tides. Organisms living in the intertidal face many
39 challenges that are unique to living at the edge of the ocean, including threat of desiccation,
40 physical wave action, and limited space. The intertidal areas of the islands are also highly
41 biologically productive and diverse, supporting diverse assemblages of algae, plants and animals.
42 Researchers have found over 200 taxa; 5 are rare and 7 were extended ranges. See Appendix H
43 for the rocky intertidal species list. The mean annual percent cover for algae and sessile
44 macroinvertebrates at the South Farallones ranges from 148-255 percent.

3. Affected Environment

1 **Perennial macrophytes** exhibit conspicuous zonation in the rocky intertidal community.
2 Microscopic algae are common in the splash zone in winter months when large waves produce
3 consistent spray on the upper portions of the rocky shore. Descending into the intertidal are
4 several zones dominated by (1) ceramial algae in the high intertidal; (2) a dense turf of erect
5 coralline and gigartinal algae in the mid-intertidal; and (3) beds of rhodymenials and laminarials
6 in the low intertidal zone. The presence of the seagrass *Phyllospadix* is a good indicator of the
7 mean low water level. In general, the rocky intertidal areas on the South Farallones are
8 predominated with red-turf and coralline algae. The most common genera at the Farallon Islands
9 include *Corallina*, crustose corallines, *Cryptopleura*, *Egregia*, *Endocladia*, *Gastroclonium*,
10 *Gelidium*, *Mastocarpus*, *Mazzaella*, *Neorhodomela*, *Petrocelis*, *Prionitis*, and *Ulva*.

11
12 Intertidal invertebrates also exhibit conspicuous zonation. The periwinkle *Littorina keenae*, and
13 the white acorn barnacle *Balanus glandula* can be used as an indicator of the splash zone. The
14 barnacle *B. glandula* and red algae *Endocladia muricata* and *Mastocarpus papillatus* are used as
15 indicators of the high intertidal zone, but these species are also found in other areas of the rocky
16 shore. At wave-exposed sites, the California mussel *Mytilus californianus* can dominate the
17 available attachment substratum in the mid-intertidal zone. Intertidal predators generally include
18 whelks (sea snails), sea stars, sea urchins, octopus, fishes, and shore crabs. Overall on the South
19 Farallones, the most common invertebrates include intertidal sea anemones *Anthopleura* and
20 molluscs *Mytilus*.

21
22 Black oystercatcher and black turnstone (*Arenaria melanocephala*) are the most common birds
23 along the rocky shoreline. The oystercatchers are resident. The turnstones are most abundant
24 during fall and winter, and during this period, are accompanied by small numbers of ruddy
25 turnstone (*Arenaria interpres*), surfbird (*Aphriza virgata*), and wandering tattler (*Tringa incana*).
26 A variety of species commonly considered landbirds also feed along rocky shores during fall and
27 winter, including black phoebe, ~~Brewer's blackbird (*Euphagus cyanocephalus*)~~ and European
28 starling.

29
30 The heads of coves on Southeast Farallon and West End include small sandy beaches. These
31 areas are prime haulout locations for northern elephant seals and California and Steller sea lions.
32 Over the past two decades a combination of elephant seal activity and large storm events have
33 caused erosion of the sand from these coves, thus reducing their use as haulouts. The diversity of
34 intertidal algae and invertebrates are greatest at some of these sandy coves, bordered by rocky
35 walls and substrate. Examples can be found at the sandy coves near Dead Sea Lion Flat and Low
36 Arch on Southeast Farallon Island.

37
38 Oil spills pose a major threat to the health and balance of life on the South Farallones' rocky
39 shores. Past spills, including the November 2007 *Cosco Busan* oil spill in San Francisco Bay,
40 have deposited oil on nearby rocky shores on the mainland. Oil can smother mussel beds and kill
41 acorn barnacles, and limpets and cause disruption in reproductive processes in invertebrates and
42 algae. Monitoring programs are vital in addressing the potential impacts, restoration and
43 recovery rates from spills.

44
45 Non-native species have also made their way to the South Farallones' intertidal zones. These
46 introductions are a major concern, due to the sanctuary's close proximity to the highly invaded

3. Affected Environment

1 San Francisco Bay. To date, almost 150 species of introduced marine algae, plants and animals
2 have been identified in the Gulf of the Farallones National Marine Sanctuary. Invasive
3 invertebrates, such as the green crab *Carcinus maenas*, make up more than 85 percent of all
4 introductions in Gulf waters. They threaten the abundance and/or diversity of native species,
5 disrupt ecosystem balance, and threaten local marine-based economies.

6
7 Marine Sanctuary staff may establish a baseline collection of intertidal survey data (particularly
8 surveys of intertidal fish taxa, which are comparatively poorly known) prior to project
9 implementation and would monitor response, either positive or negative, in the intertidal
10 community after mouse eradication.

3.4.5. Marine Mammals

3.4.5.1. California sea lion

11
12
13
14
15
16
17 California sea lions are the most abundant pinniped to haul out on the South Farallones. There
18 are probably roughly between 1,000 and 3,300 animals present on the island and in surrounding
19 waters year-round, with peak numbers from May through August (Ainley and Allen 1992, PRBO
20 unpubl. data). California sea lions breed during the summer months of May through July with the
21 majority of pups being born in June (Wilson and Ruff 1999). However, the South Farallones are
22 not a major breeding site and only a few pups have been born in recent decades. Most California
23 sea lions that are found on the Farallones breed either on the California Channel Islands or on
24 islands off the coast of Mexico (Sydeman and Allen 1997). California sea lion abundance has
25 increased substantially at the South Farallones over the last quarter century. Based on pup
26 counts, southern California populations had an estimated 5.2% annually growth rate between
27 1975 and 1994 (NOAA 1997). West coast population estimates of California sea lions in 1994
28 range from 161,066 and 181,355 (Barlow et al. 1995).

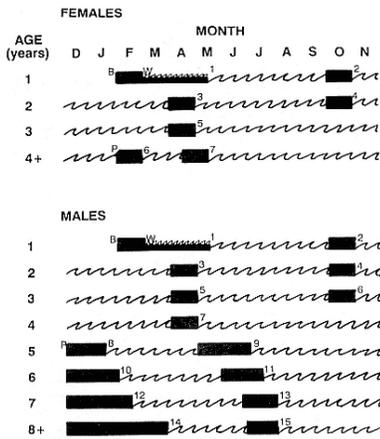

3.4.5.2. Northern elephant seal

29
30
31
32 Northern elephant seals has been recovering from their near extinction in the 19th century, which
33 was caused primarily from overharvesting for their blubber. The current elephant seal colony at
34 the Farallones began in 1959 with one individual and grew to 100 individuals by 1971. The
35 colony grew rapidly during the 1970s, and in 1983 a record 475 pups were born on the South
36 Farallones (Stewart et al. 1994). Since then, the size of the South Farallones colony has declined;
37 however, the population currently appears stable (Sydeman and Allen 1999). In 2007, a total of
38 179 cows were counted on the South Farallones, and 132 pups were weaned (Lee 2007). Annual
39 counts from 2000-2009 range from 10-1,000 individuals on the islands per month (PRBO
40 unpubl. data). The current International Union for Conservation of Nature (IUCN) status of the
41 species is of the lowest level, Least Concern (LC) (Vié et al. 2009).

42
43 Northern elephant seals are present on and in the waters surrounding the South Farallones year-
44 round, but they are more abundant during breeding and molting seasons (Le Boeuf and Laws
45 1994, Sydeman and Allen 1997). In mid-December, adult males begin arriving on the South
46 Farallones closely followed by pregnant females on the verge of giving birth. Females give birth
47 to a single pup, generally in late December or January (Le Boeuf and Laws 1994), nurse their

3. Affected Environment

1 pups for approximately 4 weeks (Reiter et al. 1978), and copulate until March (conceiving pups
 2 that will not be born until the following winter), when they leave the islands to forage in deep
 3 offshore waters. The spring peak of elephants seals on the rookery occurs in April, when females
 4 and immatures (animals one to four years old) arrive again at the colony to molt (a one month
 5 process). The year's new pups remain on the island through both of these peaks, generally
 6 leaving by the end of April. In May, the majority of animals leave the island to forage during the
 7 summer and fall. The lowest numbers of elephant seals present on the rookery occurs during
 8 June, July, and August, when adult males molt. By early September, most adult males have left
 9 forage at sea in preparation for the upcoming breeding season. Juveniles (one to 4 years of
 10 age) return to the rookery for a haulout period in October, some of which undergo partial
 11 molt (Le Boeuf and Laws 1994). See figure 3.X from Le Boeuf 1994.

13 Fig. 3.X. Annual distribution of time spent on land and at sea for male and female
 14 northern elephant seals from birth to adulthood. Solid bars represent time
 15 on land, waves represent time at sea, bars and waves represent initial water
 16 experience prior to departure from the rookery. B = birth, W = weaning,
 17 P (for females) = parturition, P (for males) = puberty. Primiparity in females
 18 occurs at 3, 4, or 5 years of age. The numbers in the figure denote the consecutive trips to sea by each sex.
 19 From Le Boeuf 1994.

22 3.4.5.3. Pacific harbor seal

25 Pacific harbor seals are one of the most common pinnipeds in California and are present on or
 26 around the South Farallones year-round (NOAA 1997). Their populations have increased
 27 significantly since the MMPA was established in 1972 (NOAA 1997), and the mid-90's
 28 population was estimated at 30,000 in California alone (Wilson and Ruff 1999). Harbor seal
 29 abundance at the Farallones appears to fluctuate largely based on food availability in waters
 30 closer to shore; harbor seals are generally most abundant directly off the mainland coast, but they
 31 venture out to the Farallones when food near the coast is scarce (Sydeman and Allen 1997).
 32 Female harbor seals give birth to one pup per year, which occurs between April and May in

3. Affected Environment

1 California (Wilson and Ruff 1999);between 1 and 3 pups are born on the South Farallones each
2 year (PRBO unpubl. data). Pups are weaned at three-six weeks and breeding generally takes
3 place two weeks later (Wilson and Ruff 1999). Harbor seal abundance has increased at the South
4 Farallones ~~during the last quarter century~~, averaging a growth rate of 15.9% per year from 1973-
5 1985, yet leveling off to 9.0% from 1985-1997 (Sydeman and Allen 1999). This increase in
6 abundance is thought to be largely the result of immigration from coastal waters (Sydeman and
7 Allen 1997). Average numbers of harbor seals on the Farallones each month ranged from 0 to
8 almost 200 individuals in 2000-2009 (PRBO unpubl. data). .

9 10 3.4.5.4. Northern fur seal

11
12 Northern fur seals are ~~also~~ present year-round in the waters surrounding the South Farallones.
13 They are most commonly seen during the fall season, although the monthly average number of
14 northern fur seals sighted is generally less than 40 (Pyle et al. 2001, PRBO unpubl. data). During
15 2000-2009, fur seal numbers ranged from 0 to almost 200 individuals, peaking during the
16 breeding season (Wilson and Ruff 1999). Although the Farallones were a major northern fur seal
17 breeding area before the arrival of hunters in the early 19th century, the species was essentially
18 extirpated from the region by the second half of that century. Not until 1996 did northern fur
19 seals begin breeding again on the Farallones (Pyle et al. 2001), and each year since then they
20 have bred in generally small numbers on West End during the summer. These numbers have
21 increased ~~dramatically~~ in recent years, with nearly 200 animals observed in 2006 (PRBO unpubl.
22 data). Male fur seals generally come ashore in late May or June to prepare for the breeding
23 season. Females come ashore in late June or July and give birth to one pup per year, and soon
24 thereafter breeding occurs (Wilson and Ruff 1999).

25 26 3.4.5.5. Steller sea lion

27
28 Steller sea lions are primarily a species of the far north Pacific, and their colony on the South
29 Farallones is near the southern end of their breeding range (Steller sea lions also currently breed
30 at Año Nuevo and previously bred at the Channel Islands). Steller sea lion began recolonizing
31 the Farallones in the mid 1970's, which was once part of their historic range (Sydeman and Allen
32 1999).Steller sea lions are present on and around the South Farallones year-round, but their
33 numbers are considerably greater during the summer breeding season and again in late fall
34 (Hastings and Sydeman 2002). Monthly averages of Steller sea lion counts range from a few
35 individuals to nearly 400 (PRBO unpubl. data). Steller sea lion breeding on the South Farallones
36 primarily occurs on West End Island, although breeding sites have shifted over the years. The
37 South Farallones breeding colony has become less productive ~~over the past quarter century~~
38 generally only between 5 and 10 pups are born annually compared with 20 to 30 pups annually
39 during the 1970s (Sydeman and Allen 1997). In general, the Steller sea lion population using the
40 South Farallones for breeding and resting has undergone a major decline ~~in the past quarter~~
41 ~~century~~. The reasons for this decline are unclear; it is possible that some adult animals have
42 merely shifted their geographic range northwards (Hastings and Sydeman 2002). Regardless, the
43 status of Steller sea lions on the South Farallones is precarious, in contrast to the other pinnipeds
44 that utilize the islands. See Appendix E for a map of Steller sea lion distribution on the South
45 Farallones.

3. Affected Environment

1 The eastern Distinct Population Segment (DPS) of Steller sea lions, which includes individuals
2 occurring in California (including the South Farallones), Oregon, Washington, Canada and
3 southeast Alaska, is listed as Threatened under the ESA. The South Farallon rookery and waters
4 around the island are designated Critical Habitat under the ESA (50 CFR 226.202). In addition to
5 the island, the Critical Habitat designation includes the waters and air space within a radius of
6 3,000 feet of the rookery. The Steller sea lion was listed as Federally Threatened under the ESA
7 in 1990 due to an 80 percent decline in the U.S. population between the 1950s and 1990. In
8 1997, after new genetic information revealed the existence of significant stratification between
9 regional populations, management of Steller sea lions under the ESA was split among two
10 distinct population segments (DPS), the western DPS and the eastern DPS. The western DPS,
11 which is primarily composed of Steller sea lions in the Aleutian Islands, was up-listed to
12 Endangered at that time. The eastern DPS, which includes Steller sea lions on the South
13 Farallones, remained listed as Threatened.

14
15 Over the past 20 years, the eastern DPS overall population has been increasing, but most of this
16 increase has occurred in southeast Alaska and British Columbia with population counts in
17 California remaining stagnant or decreasing (NMFS 2008). The reasons for ongoing population
18 declines in California are unclear; however, the growing population of California sea lions in this
19 region may be out-competing Steller sea lions. This in combination with changing oceanic
20 conditions that are negatively affecting food availability for Steller sea lions but not for
21 California sea lions may be contributing to the overall decline (NMFS 2008).

22 23 3.4.5.6. Other marine mammals in the Gulf of the Farallones

24
25 In addition to the marine mammals discussed above, Guadalupe fur seals (*Arctocephalus*
26 *townsendi*) and southern sea otters (*Enhydra lutris nereis*) have on rare occasions been spotted
27 on the islands or in the waters surrounding the Farallones (Brown and Elias 2008). The rarity
28 with which these species occur precludes them from detailed analysis in this document.

29
30 There are also a number of cetacean species that inhabit the Gulf of the Farallones including
31 grey, blue and humpback whales, but they are very unlikely to be affected by any of the actions
32 described and analyzed in this document, because all project activities would occur on or directly
33 above the islands themselves and not in the surrounding marine environment.

34 35 3.4.5.7. Special legal protection for marine mammals at the South Farallones

36
37 All of the regularly-occurring marine mammals at the South Farallones are protected from harm
38 under the Marine Mammal Protection Act (MMPA). The Steller sea lion is listed as depleted
39 throughout its range and is also listed as threatened under the ESA.

40 41 42 **3.4.6. Terrestrial Vegetation**

43
44 The vegetation diversity on the Farallon Islands is low compared to the nearby mainland due to
45 the harsh marine environment. Sparse soil coverage, guano, and continuous trampling by
46 seabirds and pinnipeds further limits the extent of vegetation on the Farallones. The islands' flora
47 includes at least 44 species, 26 of which are non-native (Coulter and Irwin 2005). Maritime

3. Affected Environment

1 goldfields cover much of Southeast Farallon Island. Maritime goldfields are specialized for life
2 on offshore seabird colonies, occurring on islands, sea stacks and coastal cliffs along the Pacific
3 coast of North America from San Luis Obispo County, California to Vancouver Island, British
4 Columbia. They are tolerant of the caustic soil conditions that are characteristic of guano-
5 covered seabird habitat (Crawford et al. 1985, Vasey 1985).

6
7 In the most recent study conducted in 2005, 26 different non-native plants were recorded
8 (Coulter and Irwin 2005) several of which are harmful pests. These include two non-native grass
9 species which currently dominate Southeast Farallon's southeast end (great brome *Bromus*
10 *diandrus* and hare barley *Hordeum murinum leporinum*), New Zealand spinach (*Tetragonia*
11 *tetragonoides*), least mallow (*Malva parviflora*), and buck's horn plantain (*Plantago*
12 *coronopus*). Most non-native plants are found on the marine terrace in the south and southeast
13 portions of Southeast Farallon and up the south-facing slopes of Lighthouse Hill and Little
14 Lighthouse Hill. The spread of some of these non-native plants to the northern side of the island
15 could pose a further threat to native species and habitats. New Zealand spinach has been
16 identified as a particularly serious threat to the Farallones ecosystem because its impenetrable
17 mats of growth degrade seabird burrowing and nesting habitats (USFWS 2005b).

Comment [g98]: List some of the management efforts to control NZ spinach!

18
19 Several trees (Monterey cypress *Cupressus macrocarpa* and Monterey pine *Pinus radiata*) were
20 planted on Southeast Farallon Island before the island was added to the Refuge. There are two
21 Monterey cypress individuals that were planted in 1982 (Pyle and Henderson 1991) near the
22 houses. There are also three "cultivated patches" of bush mallow (*Lavatera arborea*), a non-
23 native species, near the housing units and near the east end of the Marine Terrace (Pyle and
24 Henderson 1991). The islands' few landbirds largely congregate in the immediate vicinity of
25 these larger plants.

26
27 Much of the native vegetation on the Farallones senescens or dies by the summer and rebounds in
28 the early winter and spring when seasonal rainfall begins. Several non-native species, such as
29 New Zealand spinach, grow year-round.

3.5. Social and Economic Environment

3.5.1. Ownership/Management/Major Stakeholders

34
35
36 The South Farallones are managed as the Farallon National Wildlife Refuge, part of a national
37 system of Federal lands managed by the Service for the primary benefit of wildlife and their
38 habitats. However, the U.S. Coast Guard's authority to use Southeast Farallon Island for a
39 navigational light station pre-dates and supersedes the Service's jurisdiction. Coast Guard
40 personnel visit the island about twice a year to maintain the automated, solar-powered light at the
41 top of Lighthouse Hill, and rarely become involved in management of the island. The
42 surrounding waters are managed primarily by the National Oceanic and Atmospheric
43 Administration (NOAA) as the Gulf of the Farallones National Marine Sanctuary. The waters
44 surrounding the islands out to a distance of one mile are designated as the Farallon Islands State
45 Marine Conservation Area by the California Department of Fish and Game. Between March 15
46 and August 15 boat traffic is also prohibited within 300 ft. of designated sections of the

3. Affected Environment

1 shoreline. The Department of Fish and Game is in the process of establishing a no-take Marine
2 Reserve surrounding the South Farallones, which will also include a year-round Special Closure
3 area encircling the island except in limited areas during the fall.

Comment [g99]: Check on the status!!!

4
5 Due to the sensitive nature of the wildlife and the difficulty of landing on the islands, access to
6 the South Farallones is strictly monitored and currently limited to FNWR and PRBO
7 Conservation Science staff, their approved contractors and collaborators, special-use-permit
8 holders, and the US Coast Guard. ~~Except as prohibited above,~~ vessels use the East Landing and
9 less often ~~the North Landing~~, as calm-weather anchorages.

10
11 The South Farallones are within San Francisco County limits, but the islands do not provide any
12 employment opportunities for the general public. The waters ~~surrounding~~ the island are
13 harvested by commercial fishing operations. Wildlife-viewing and sport-fishing charter boats,
14 none of them operated by the Service, also generate income for the region. Fishing will no longer
15 be permitted within the soon-to-be-established Southeast Farallon Island Marine Reserve.

Comment [g100]: Is is allowed now?

ADMINISTRATIVE REVIEW

3. Affected Environment

3.5.2. Recreational and Aesthetic Uses

There are currently no recreation opportunities available to the public on land due to the presence of sensitive wildlife and habitat. However, the immediate surrounding waters provide an estimated 3,500 “wildlife viewing visitor days” annually (USFWS 2005a). Several wildlife-viewing boats conduct natural history tours throughout the year (weather permitting) out to the waters surrounding the islands. These tours focus on seabirds, marine mammals, and sharks. The wildlife-viewing opportunities associated with the Farallones extend to the nearby mainland coast, as well as, to some of the seabird species that breed on the Farallones and forage near the mainland.

For several major species – notably nearshore rockfishes, surfperches, greenlings, lingcod, flatfishes, salmonids, and sculpins – north-central California accounts for a majority of the statewide recreational catch. Generally speaking, recreational fisheries provide considerable value to coastal economies. Based on the average annual number of fishing trips of residents and nonresidents in 1998-99, aggregate annual expenditures related to marine recreational fishing, including costs for gear, licenses, and other supplies, amounted to \$570 million (in 2003 dollars), \$200 million of which derived from fishing activity in north-central California (Scholz and Steinback 2006).

In addition to guided tours and recreational fishing, there are other private pleasure boats that use the waters surrounding the South Farallones. However, due to the often-unsettled nature of the weather and seas, general recreational boating is much less common outside of the Golden Gate than it is within the protected waters of the San Francisco Bay.

3.5.3. Commercial Fisheries

The waters surrounding the South Farallon Islands are currently productive grounds for commercial fishing. Scholz and Steinback (2006) conducted an in-depth examination of the use of the adjoining National Marine Sanctuaries that span the coast of central California as fishing resources. Currently, the most important fisheries in the study area (the Cordell Bank and Gulf of the Farallones and adjacent port communities from Bodega Bay to Pillar Point, Half Moon Bay) are Dungeness crab, groundfish (including several nearshore species), herring, salmon, squid, tuna, and urchins. Between 1981 and 2003, these seven fisheries yielded an average of nearly 35 million pounds of landings worth over \$31 million per year (in constant 2003 dollars).

In general, the fisheries in the study area are more valuable than in the state as a whole. Over the past 23 years, the proportion of revenues derived from commercial fisheries’ landings in study-area ports has increased, from 5 percent of the state total in 1981 to several times that number in recent years.

Overall, commercial fisheries are conducted with fewer vessels than a generation ago. Since the most recent peak of commercial fisheries in 1981, the number of fishing vessels in California has declined steadily. The number of vessels making landings in study-area ports has similarly declined, from 2,200 in 1981 to 603 in 2004. Fewer than half of these vessels are responsible for

3. Affected Environment

90 percent of landed catch. The fisheries are not just losing vessels. In general, fishermen report that there are fewer young people entering the fisheries.

The waters immediately surrounding the South Farallones will soon be designated a no-take Marine Reserve by the State of California. Fishing will not be permitted within the Reserve.

Comment [JS101]: More info needed: Effective date? Marine Reserve boundaries?

3.5.4. Historical & Cultural Resources

The South Farallones have had extensive human activity beginning as a marine mammal hunting ground, a coveted egg gathering site, a manned Coast Guard light station, and a military outpost. These past activities have left behind many remnant elements that may possess some level of cultural significance. Thus, the entire Southeast Farallon Island was listed on the National Register of Historic Places in 1977. This designation did not specifically identify significant structures or other elements. Instead, structures and elements are evaluated for their historic significance when the structure is being considered for rehabilitation or renovation. Not every element on the islands has been evaluated. Specific structures that have been determined to be culturally significant include the 2 residences, a carpenter’s shop, the lighthouse trail, and the rail cart system. The oldest structural remains on the South Farallones are thought to be the Russian House foundation, which was used by seal hunters. The area surrounding the Russian House foundation also has the highest concentration of historic marine mammal bones on the island.

There are numerous artifacts from the islands’ 19th century history as an important source of eggs for the rapidly growing San Francisco region. The infamous Farallon Egg Wars were fought here in 1863 (White 1995, Wake and Graesch 1999). Another area with significant eggging history is the stone enclosures and wall south of North Landing. These structures were used by eggers for cleansing and storage of eggs (Wake and Graesch 1999). Russian era shelters and eggers barracks also contain a high frequency of surface artifacts and mid-19th century bottle glass. Sewer Gulch and Garbage Gulch served as dump sites in the later part of the 19th century. Many archaeological deposits are still present in these areas that help to provide insight into early human occupation on the island.

Figure 3.2. Southeast Farallon residences as seen from Lighthouse Hill.

The 2 existing residences were built in 1860 to accommodate lighthouse crews, which were limited to men and then eventually families. The architect is unknown, but the houses are good examples of 19th century institutional architecture. These residences were extensively altered around 1959, but renovations in 1999 returned them closer to their original appearance. The two residences are considered culturally significant and are included in the National Register of Historic Places. Moreover, the function of these houses as

3. Affected Environment

1 residences still continues for PRBO biologists, Refuge staff, and other visiting researchers and
2 contractors today. Rock features in front of one of the houses could potentially represent a
3 prepared butchering area for preparation of marine mammals and other prey (Wake and Graesch
4 1999).

5
6 During habitation by the lighthouse crew, the rail cart system on Southeast Island was an
7 important vehicle for transporting goods from ships to the main structures. The rail cart system is
8 estimated to have been built in about 1878 to connect the North Landing with the residences and
9 coal storage. The line was later extended to the East Landing. The system carried coal and other
10 freight from the landing to the quarters by mule power and was never motorized. The last mule
11 was used in 1913 and since then, carts have been powered by residents. The portion of the rail
12 system that remains running from East Landing to the housing units, is considered culturally
13 significant because it represents a certain function during a historic period (1878-1939). Due to
14 harsh environmental conditions and replacement by other means, the rail cart system has been
15 maintained only modestly.

16
17 The building now called the Carpenter Shop was constructed by the U.S. Navy in 1905 as
18 barracks and was occupied until about 1945. The structure was evaluated in 2005 and is
19 considered a significant cultural element because it is the only standing building that represents
20 the Navy period.

21
22 While the water catchment area is not considered culturally significant, the area surrounding it
23 may contain high potential sub-surface artifacts and features that should be carefully traversed to
24 prevent potential damage (Valentine 2000).

25
26 The wooden water tanks and foghorn remnants have not been evaluated to determine their
27 historical significance. However, the foghorn should be noted as the island's first attempt at
28 providing a navigation warning.

29
30 A limited amount of aboriginal artifacts are present on the Southeast Farallon Island. Some
31 artifacts are ascribed to Aleut or Northwest Coast origin, while others are associated with
32 California Native Americans. Those items that were manufactured by Native Americans were
33 thought to be associated with the Russian fur traders and their various Native American
34 employees. Other cultural pieces including bones from elk, deer, and pig indicates that occupants
35 relied on meat from the mainland.

4 Chapter 4: Environmental Consequences

4.1 Purpose and Structure of this Chapter

Chapter 4 analyzes the environmental consequences of the alternatives as presented in Chapter 2. For comparative purposes, Chapter 4 also includes a similar analysis of the consequences of taking no action to address the problem of non-native house mice on the resources of the South Farallones. The purpose of the impacts analysis in this chapter is to determine whether or not any of the environmental consequences identified may be significant.

The concept of significance, according to CEQ regulations (40 CFR 1508.27), is composed of both the *context* in which an action will occur and the *intensity* of that action on the aspect of the environment being analyzed. “Context” is the setting within which an impact is analyzed, such as a particular locality, the affected region, or society as a whole. “Intensity” is a measure of the severity of an impact. Determining the intensity of an impact requires consideration of the appropriate context of that impact as well as a number of other considerations, including the following:

5. Impacts may be both *beneficial* and *adverse*. A significant effect may exist even if on balance the effect will be beneficial.
6. The degree to which an action affects *public health or safety*.
7. *Unique characteristics of the geographic area* (e.g. historical or cultural significance, specially protected lands, ecologically critical areas).
8. The degree to which the impacts of an action are likely to be *highly controversial*. The courts have since elaborated on this consideration, stating that controversy would be in the form of “substantial dispute” as to “the size, nature or effect of the major Federal action rather than to the existence of opposition to a use [e.g. eradication of mice], the effect of which is relatively undisputed” (*Hanly v. Kleindienst*, 471 F.2d 823, 830 [2d Cir. 1972]).
9. The degree to which the possible impacts of an action are *highly uncertain, or involve unique or unknown risks*.
10. The degree to which an action may i) *establish a precedent* for future actions with significant effects; and/or ii) *represents a decision in principle* about a future consideration.
11. Whether an action is related to other actions with individually insignificant but *cumulatively significant impacts*. Significance exists if it is reasonable to anticipate a cumulatively significant impact on the environment.
12. The degree to which an action may adversely affect properties listed in or eligible for listing in the National Register of Historic Places, or may cause *loss or destruction of significant scientific, cultural, or historical resources*.
13. The degree to which an action may *adversely affect an endangered or threatened species or critical habitat as listed under the ESA*.
14. Whether the action *threatens a violation of Federal, State, or local law* or requirements imposed for the protection of the environment.

4. Environmental Consequences

4.2 Environmental Issues (Impact Topics) Addressed

4.2.1 Scoping for Environmental Issues (Impact Topics)

The Service compiled a list of major environmental issues, or impact topics that warranted specific consideration in this analysis. The compilation of this list of issues was informed by a scoping process that included informal discussions with representatives from numerous government agencies, private groups and individuals with relevant expertise or a stake in the Farallon Islands, and solicitation of public comments (see Section 1.6.1 and Section 5.3-6).

In the analysis below, the potential significance of effects of each action alternative and the no action alternative will be discussed on a case-by-case basis for each environmental issue considered.

4.2.2 Impact Topics

The impact topics analyzed in this document include:

- Impacts to physical resources
 - Impacts to water resources
 - Impacts to geology and soil
 - Impacts to wilderness character
- Impacts to biological resources
 - Impacts to Birds
 - Impacts to Mammals
 - Impacts to Amphibians
 - Impacts to Fish
 - Impacts to Invertebrates
 - Impacts to Vegetation
- Impacts to the social and economic environment
 - Impacts to refuge visitors and recreation
 - Impacts to fishing resources
 - Impacts to historical and cultural resources
- Cumulative impacts
- Irreversible or irretrievable commitment of resources
- Relationship of short-term uses to long-term productivity

Brief descriptions of many of these topics can be found in Section 1.6.

4.2.3 Aspects of the Environment Excluded from Detailed Analysis (with Rationale)

Air quality

Impacts of the action alternatives on air quality at the South Farallones will not be analyzed in detail because there are no activities proposed that would represent a measurable change from the background levels of air pollution caused by nearby water- and aircraft. The brief, localized

4. Environmental Consequences

1 helicopter operations that would occur as part of each action alternative would have no more
2 than a negligible contribution to local or regional changes in air quality.

3 4 *Cetaceans (e.g. whales and dolphins)*

5
6 Potential impacts of mouse eradication activities to cetaceans (whales, dolphins, and their close
7 relatives) in the waters surrounding the South Farallones will not be analyzed in this EA. The
8 likelihood of cetacean exposure to brodifacoum would be negligible. Except for small boat
9 traffic, which would be limited in duration and concentrated immediately offshore of the island,
10 all of the activities described in the action alternatives would be aerial or terrestrial. Additionally,
11 the likelihood of these activities having measurable impacts on cetaceans would be negligible
12 because they would have to consume extremely large quantities of bait to experience lethal or
13 sublethal affects.

14 15 *Environmental justice*

16
17 The impacts of the action alternatives on environmental justice (the agency mandate set in
18 Executive Order 12898 to identify and address the potential for disproportionate placement of
19 adverse environmental, economic, social, or health impacts on minority and low-income
20 populations) will not be analyzed in detail because there are no minority or low-income
21 populations that would be affected by either of the action alternatives.
22

23 **4.3 Consequences: Physical Resources**

24 25 **4.3.1 Water Resources**

26 27 *Analysis framework for water resources*

28
29 Significant water quality impacts were analyzed for the identified action alternatives with respect
30 to potentially adverse physical and biological impacts from bait application on the South
31 Farallones.

32
33 Mice on the South Farallones are frequently found on and around the shoreline. For this reason,
34 it is essential that managers apply the rodenticide all the way down to the high tide mark to
35 ensure the exposure of all rats on the entire atoll. Even though maximum effort will be taken to
36 prevent bait drift into the marine environment, permitting for aerial pesticide use around the
37 littoral zone will be sought to comply with EPA's new CWA guidelines for aerial pesticide
38 applications over waters of the United States.
39

40 Water quality in the State of California is regulated by the State Water Resources Control Board,
41 which requires all state waters to meet minimum criteria for a number of designated uses. While
42 the federal Clean Water Act (CWA) prohibits the discharge of "pollutants" into waters of the
43 United States, in 2007 the EPA clarified its interpretation of the term "pollutant" to exclude
44 pesticides that may unavoidably enter the water through bait drift while being applied to control
45 pests that occur "over, including near" water bodies (71 CFR 227 pp. 68483-68492). This ruling
46 was vacated by the 6th Circuit Court of Appeals in 2009, requiring all projects that use aerial
47 pesticide broadcast techniques over or near waters of the U.S. to comply with the CWA National

4. Environmental Consequences

1 Pollution Discharge Elimination System (NPDES) permitting process. Subsequently EPA was
2 granted a stay until April 9, 2011 to allow the agency time to determine the appropriate
3 permitting process. We will fully comply with all Clean Water Act NPDES permitting required
4 by the EPA pending the 2011 announcement.

Alternative A: No action

8 Mice on the South Farallones do not currently affect the quality or quantity of island drinking
9 water or marine water resources, nor would the Service expect any future impacts.

Alternative B: Aerial Broadcast of Brodifacoum

13 Some bait pellets would be likely to drift into nearshore marine waters during bait application
14 operations. However, the bait application techniques described would include mitigation
15 measures to limit bait drift into water bodies to a level well under the target bait application rate.

17 Even if bait does drift into the water bodies on or around the South Farallones at the full
18 application rate, it would be very unlikely to contribute to detectable levels of brodifacoum in the
19 water column. The low water solubility and strong chemical affinity of brodifacoum to the grain
20 matrix of the bait pellets largely prevents the rodenticide from entering aquatic environments via
21 run-off. Hypothetically, even if brodifacoum was highly water soluble, and bait was broadcast at
22 the rate of 16 lb/ac (18 kg/ha) into water only 3.3 ft (1 m) deep, the resultant brodifacoum
23 concentration in the water (about 0.04 parts per billion) would still be nearly 1000 times less than
24 the measured LC₅₀ value for trout (0.04 parts per million) (Syngenta Crop Protection 2003).

26 Environmental testing during rodent eradications and eradication trials in the California Current
27 marine system and elsewhere have failed to detect brodifacoum in any water samples taken after
28 bait application (Buckelew et al. 2005a, Buckelew et al. 2008a, Island Conservation unpubl.
29 data). Furthermore, post-application sampling in the Anacapa Island rat eradication did not detect
30 any brodifacoum residue in any of the intertidal invertebrates tested (Buckelew et al. 2005a).

32 Water supplies for personnel on the South Farallones would be protected during bait application
33 activities to prevent the entry of pellets into water catchment areas.

35 In summary, there would be a negligible risk that the marine water column or drinking water
36 supplies would register biologically harmful, or even detectable, levels of brodifacoum as a
37 result of bait application to the island.

Alternative C: Brodifacoum Deliver Primarily Through Bait Stations

41 Bait from bait stations would not be likely to drift into water bodies on or around the South
42 Farallones. During aerial bait application of inaccessible areas, the risk profile under Alternative
43 C would be similar to that of Alternative B described in Section 4.3.1.3.

Alternative D: Phased Aerial Broadcast of Brodifacoum

4. Environmental Consequences

1 During aerial bait application of inaccessible areas, the risk profile under Alternative D would be
2 similar to that of Alternative B described in Section 4.3.1.3.

4.3.2 Geology and Soils

Analysis framework for geology and soils

8 The major issues of concern for the geology and soil resources of the Farallones are 1)
9 permanent damage to granitic rock formations, 2) increases in soil erosion, and 3) contamination
10 of soils.

Alternative A: No action

14 Under the no action alternative, mice would remain on the island and would continue to burrow
15 in areas with a substantial soil layer. However, there are numerous seabird species that burrow
16 on the island as well, and mouse burrowing activity would not be likely to contribute to
17 noticeably more erosion than seabird burrowing. Mice would not measurably impact rock
18 formations or contamination in soils.

Alternative B: Aerial Broadcast of Brodifacoum

22 The activities in Alternative B would not have a noticeable impact on soil erosion, rock
23 formations, or soil contamination. The installation and maintenance of bait stations in limited
24 circumstances may have highly localized impacts to soil and rock but these impacts would not be
25 significant. The extremely low concentration of brodifacoum in bait pellets would not lead to
26 measurable soil contamination. In environmental monitoring after rat eradication on Anacapa
27 Island using brodifacoum pellets, all soil samples collected tested negative for brodifacoum
28 residue (Buckelew et al. 2005a).

Alternative C: Brodifacoum Deliver Primarily Through Bait Stations

32 The bait station grid required under Alternative C would have minor to moderate, localized
33 impacts on soil erosion and rock formations, but these impacts would not be significant to the
34 general soil conditions of the islands. Concurrent with soil erosion, seabird burrows would likely
35 be damaged. This impact is discussed in Section 4.4 (impacts to biological resources). Limited
36 aerial broadcast of brodifacoum pellets would not lead to measurable soil contamination.

Alternative D: Phased Aerial Broadcast of Brodifacoum

40 The activities in Alternative D would not have a noticeable impact on soil erosion, rock
41 formations, or soil contamination. The installation and maintenance of bait stations in limited
42 circumstances may have highly localized impacts to soil and rock but these impacts would not be
43 significant. The extremely low concentration of brodifacoum in bait pellets would not lead to
44 measurable soil contamination. In environmental monitoring after rat eradication on Anacapa
45 Island using brodifacoum pellets, all soil samples collected tested negative for brodifacoum
46 residue (Buckelew et al. 2005a).

4. Environmental Consequences

4.3.3 Wilderness Character

Analysis framework for wilderness character

Areas of the South Farallones are designated Wilderness as regulated by the Wilderness Act of 1964 (PL 88-577). Preservation of wilderness character is not a category of analysis required under NEPA regulations, but the special designation of several segments of the South Farallones as Wilderness will be considered through an analysis of the impacts of each action alternative. Under the Wilderness Act, an area's wilderness character is defined by the following qualities:

15. Untrammelled by human impacts;
16. Undeveloped, without permanent structures or habitations;
17. Influenced primarily by natural forces; and
18. Has outstanding opportunities for solitude or a primitive and unconfined type of recreation.

The impacts of each alternative that relate to the Wilderness Act will be discussed according to their benefit or harm to each of the above four qualities that characterize wilderness. Additionally, the Service is preparing a **Minimum Requirements Analysis** as required for projects which require the use of tools normally prohibited in Designated Wilderness.

Alternative A: No action

Since humans introduced mice to the South Farallones, they have influenced the islands' natural ecosystem. Their presence and impacts have thus degraded the wilderness character of the Designated Farallon Wilderness Area. Taking no action with regard to non-native mice on the South Farallones would allow this degradation to continue.

Alternative B: Aerial Broadcast of Brodifacoum

The aircraft and personnel activity required in the Farallon Wilderness Area under Alternative B would produce short term negative impacts on the wilderness character of West End. The eradication effort would require manipulation of the existing ecological processes in an effort to restore natural systems that have been disrupted through the introduction of a non-native species. However, the long term benefits of an enduring wilderness with restored ecological systems gained through a successful mouse eradication would be greater than the short term negative impacts the effort may have to the wilderness character of the Farallon Wilderness Area.

Alternative C: Brodifacoum Deliver Primarily Through Bait Stations

The installation and maintenance of a bait station grid in designated wilderness under Alternative C would produce short-term negative impacts on the wilderness character of West End. The operation of helicopters would contribute further to this short-term degradation. Alternative C would require a major increase in human activities within the Wilderness Area, unprecedented since the Service assumed responsibility for the South Farallones. While personnel would make an effort to minimize the spread of non-native plants to the Wilderness Area, the risk of new introductions would be increased from current use patterns. In addition, the mouse eradication effort would require manipulation of the existing ecological processes in an effort to restore

Comment [g102]: Has FWS started working on this? Does IC need to prepare anything for this requirement?

4. Environmental Consequences

1 natural systems that have been disrupted through the introduction of a non-native species. These
2 impacts would have the potential to decrease a Refuge visitor's opportunity to experience
3 solitude. However, the long term benefits of an enduring wilderness with restored ecological
4 systems gained through a successful mouse eradication would be greater than the short term
5 negative impacts the effort may have to the wilderness character of the South Farallones
6 wilderness areas.

7 8 *Alternative D: Phased Aerial Broadcast of Brodifacoum*

9
10 The aircraft and personnel activity required in the Farallon Wilderness Area under Alternative D
11 would produce short term negative impacts on the wilderness character of West End. The
12 eradication effort would require manipulation of the existing ecological processes in an effort to
13 restore natural systems that have been disrupted through the introduction of a non-native species.
14 However, the long term benefits of an enduring wilderness with restored ecological systems
15 gained through a successful mouse eradication would be greater than the short term negative
16 impacts the effort may have to the wilderness character of the Farallon Wilderness Area.

17 18 **4.4 Consequences: Biological Resources**

19 20 **4.4.1 Introduction**

21
22 In order for the project to be considered a restoration success, the long-term benefits of mouse
23 eradication must outweigh any potential ecosystem costs. The eradication of mice is expected to
24 have benefits for a number of animals and plants that are currently being negatively affected by
25 mouse presence. However, it is also critical to identify the potential biological impacts of the
26 actual eradication operations, including mortality and injury to sensitive wildlife species as a
27 result of ingestion of rodenticide or disturbance from project operations. Furthermore, it is
28 important to identify any biological resources that are currently dependent on the non-native
29 mice in some way and may be negatively affected once mice are removed. This document's
30 analysis of impacts to biological resources will identify both the benefits (positive effects) and
31 the costs (negative effects) of mouse eradication.

32
33 While the impacts of each alternative to the biological resources of the South Farallon Islands
34 will be examined with respect to individual animals, the primary focus will be to analyze
35 whether impacts to a particular resource (species or taxonomic group) could be considered
36 significant according to the general significance criteria described in Section 4.1. The concept of
37 significance will be defined separately for each topic analyzed below. In some cases, after all
38 relevant considerations are taken into account; impacts at the individual level (i.e. causing
39 mortality or behavior changes to individual animals) must be considered significant. One
40 example of this case is species that are listed under the ESA. However, in the case of many of the
41 taxa analyzed here, impacts to individual organisms, however major, may not qualify as
42 significant impacts in the context of population-level impacts to species utilizing the South
43 Farallones. In other words, for species that have large populations, a wide range, and are capable
44 of rapidly recovering from losses, impacts to individuals are usually unlikely to harm the
45 population as a whole. The results of risk analyses for individual animals will contribute to the

4. Environmental Consequences

1 overall analysis of significance for each biological taxon considered, but they should not be
2 considered interchangeable with the significance determination for each impact topic.

3
4 While the impacts of each alternative can be analyzed with considerable confidence over the
5 short term, it is more difficult to accurately predict specific long-term responses to mouse
6 eradication. While the determination of the overall ecosystem response to mouse eradication on
7 the South Farallones includes too many variables to analyze with precision in this document,
8 data from other island mouse eradications can be used to predict long-term ecosystem responses.
9 Whenever possible, these data will be used to help determine long-term effects in the analysis
10 sections below.

11 **4.4.2 Assessing Significance of Impacts to Biological Resources**

12
13
14 As described in Section 4.1, the concept of significance is shaped by both the context of an
15 action and the intensity of the action's effects. In the case of the action alternatives analyzed
16 here, the action itself has a very limited, site-specific context. However, many of the species that
17 utilize the South Farallones have large ranges or interact, at a population level, with other
18 individuals that may be spread out over an area much larger than the South Farallones.
19 Therefore, the most appropriate context within which to consider impacts to biological resources
20 is at the population level rather than individual organisms. The intensity of effects is dependent
21 on numerous variables that are different for each taxon. This analysis will focus on additional
22 legal protection (ESA and MMPA listings) as the primary defining criterion for determining the
23 intensity of an impact to a species; in other words, impacts to species that have been assigned
24 specific legal protection under ESA or MMPA will be considered for the purpose of this analysis
25 as "more intense" than similar impacts would be to unlisted species.

26
27 For all biological resources analyzed, except those identified in the "special considerations"
28 below, the potential for significance will be determined using the following guidelines:

- 29 • Is there a high likelihood that the population of an organism will experience noticeable
30 changes that will be measurable throughout their range?
- 31 • Is there a high likelihood that impacts on organisms at the South Farallones will be
32 measurable elsewhere in the region?

33 *4.4.2.1 Special significance considerations for ESA-listed species*

34
35
36 There is one species that is likely to occur on the South Farallones that is on the Federal
37 Endangered Species list, the eastern DPS of the Steller sea lion is listed as Threatened. Listing
38 under ESA provides a context for impacts analysis which lowers the threshold of significance.
39 This analysis will identify any ESA-listed species and any ESA-designated critical habitat that
40 may be affected by the preferred alternative. The significance of these impacts will be
41 determined separately, but the ESA-listed status of the species affected will be given special
42 weight.

- 43
44 • For **Steller sea lions**, the significance threshold for effects will be set at an action that
45 causes the significant potential for mortality in an individual animal.

Comment [g103]: Are there any other ESA listed species?

4. Environmental Consequences

1 Endangered Species Act regulations also oblige Federal agencies to ensure that the actions they
2 take are not likely to “jeopardize the continued existence of a listed species or result in the
3 destruction or adverse modification of designated critical habitat” (ESA Section 7(a)2). If a
4 Federal action may adversely affect an ESA-listed species or its designated critical habitat, the
5 action agency must initiate a formal process of consultation with the National Marine Fisheries
6 Service (NMFS) for Steller sea lions to determine whether or not the action will put the
7 potentially affected species in jeopardy of continued survival. Additionally, if individual animals
8 that are listed under the ESA are likely to be “taken” by the agency’s action, the Service must
9 apply for an Incidental Take Permit, which allows managers to implement a project that may
10 incidentally affect listed species that are not the target of the management action.

11 4.4.2.2 *Special significance considerations for marine mammals under the Marine Mammal Protection* 12 *Act (MMPA)*

13
14 Listing under MMPA provides a context for impacts analysis which lowers the threshold of
15 significance. The MMPA regulations generally prohibit the killing, injury, or disturbance of
16 marine mammals, but permits can be granted allowing exceptions to this prohibition for actions
17 that may impact a marine mammal if the impact is incidental to rather than the intention of the
18 action. This analysis will identify the potential for impacts to marine mammals that may require
19 additional permits under MMPA.
20

21 The significance of these impacts will be determined separately, but the MMPA-listed status of
22 the species affected will be given special weight. For marine mammals, the significance
23 threshold for effects will be set at an action that causes the significant potential for mortality in
24 an individual animal. MMPA regulations prohibit “disturbance” of marine mammals, which is a
25 lower threshold of impact than mortality. Disturbance according to the MMPA definition will not
26 alone constitute a significant impact in this analysis, but other potential circumstances (including
27 cumulative impacts analysis) may nevertheless contribute to an overall determination of
28 significant impacts.
29

- 30
31 ■ For California sea lion (*Zalophus californianus*), the significance threshold will be set
32 according to the MMPA’s definition of Level A Harassment: “any act which injures or has
33 the significant potential to injure a marine mammal or marine mammal stock in the wild”
34 (MMPA 515.18(A)).
35
- 36 ■ For Stellar sea lion (*Eumetopias jubatus*), the significance threshold will be set according to
37 the MMPA’s definition of Level A Harassment: “any act which injures or has the significant
38 potential to injure a marine mammal or marine mammal stock in the wild” (MMPA
39 515.18(A)).
40
- 41 ■ For harbor seal (*Phoca vitulina*), the significance threshold will be set according to the
42 MMPA’s definition of Level A Harassment: “any act which injures or has the significant
43 potential to injure a marine mammal or marine mammal stock in the wild” (MMPA
44 515.18(A)).
45
- 46 ■ For northern elephant seal (*Mirounga angustirostris*), the significance threshold will be set
47 according to the MMPA’s definition of Level A Harassment: “any act which injures or has

4. Environmental Consequences

1 the significant potential to injure a marine mammal or marine mammal stock in the wild”
2 (MMPA 515.18(A)).

- 3
- 4 ■ For northern fur seal (*Callorhinus ursinus*), the significance threshold will be set according
5 to the MMPA’s definition of Level A Harassment: “any act which injures or has the
6 significant potential to injure a marine mammal or marine mammal stock in the wild”
7 (MMPA 515.18(A)).
8

9 4.4.2.3 Special significance considerations for birds listed under the Migratory Bird Treaty Act (MBTA)

10 Listing under the Migratory Bird Treaty Act (MBTA) provides a context for impacts analysis
11 which lowers the threshold of significance for this analysis. Take under the MBTA includes the
12 unlawful pursuit, hunt, take, capture, or kill, of any migratory bird, nest, or egg of any such bird.
13 MBTA listed species that are found near or around Palmyra will be given special significance
14 thresholds to minimize negative impacts to listed birds. All of the birds found on Palmyra Atoll
15 are listed for protection under the MBTA. Therefore, the significance threshold for impacts to
16 birds will be set at an action that causes the mortality of an individual animal.
17

18 Under certain circumstances where the goal is eradicating or controlling invasive species, the
19 FWS will provide practitioners with a Special Purpose Permit under the MBTA that allows for
20 the take of listed individuals for “projects where the applicant demonstrates expected benefits to
21 migratory birds. These projects support the Service’s bird conservation mandate and mission
22 and are consistent with the Administration’s emphasis on control of invasive species” (FWS
23 2010). The Service will comply fully with all MBTA requirements prior to the implementation
24 of any of the 5 action alternatives.
25

26 4.4.3 Impacts of Alternative A (No Action) on Biological Resources

27 4.4.3.1 Introduction

28 If no action is taken regarding non-native house mice on the South Farallones, the impacts that
29 mice are having to the islands’ biological resources would continue. This section will summarize
30 the impacts that are known and suspected to numerous aspects of the South Farallones
31 environment. Additionally, this section will describe the possibility of new environmental
32 impacts from mice emerging in the future, as has occurred on other islands where house mice
33 were introduced.
34

35 4.4.3.2 Mouse impacts to terrestrial and intertidal foragers

36 4.4.3.2.1 Impacts to burrowing owls

37 The presence of mice on the Farallones makes the islands a population sink for burrowing owls.
38 The burrowing owls that have been documented overwintering on the South Farallones and
39 preying on storm-petrels have largely been juveniles. Although burrowing owls of all ages arrive
40 on the islands when they become lost at sea during their fall migration, most leave shortly after
41 and usually only a small number of burrowing owls ultimately remain into the winter. Island
42 biologists tracking these owls find most of them dead by the spring. While some of these owls
43
44
45
46
47

4. Environmental Consequences

1 are killed by western gulls, which become extremely territorial during their spring breeding
2 season, others are found dead of probable malnutrition (PRBO pers. comm.). The California
3 Department of Fish & Game has designated the burrowing owl as a Species of Special Concern.
4 On its own, burrowing owl mortality on the Farallones is unlikely to have population-level
5 impacts to burrowing owls, but it may contribute to cumulative negative impacts to the species
6 along with other threats on the mainland.

7 8 4.4.3.2 Impacts to salamanders

9
10 The endemic Farallon arboreal salamander has a diet similar to house mice on the South
11 Farallones, so when the mice are abundant each summer and fall on the island they may limit the
12 amount of food available to salamanders. Furthermore, the food preferences of introduced mice
13 on other islands (Newman 1994) indicate that mice on the South Farallones could prey directly
14 on salamanders but the effect of such predation is unknown.

15 16 4.4.3.3 Impacts to invertebrates

17
18 Invertebrates comprise a major portion of the diet of mice on the South Farallones (Jones and
19 Golightly 2006). Comparisons to other islands with introduced house mouse populations (Rowe-
20 Rowe et al. 1989, Crafford 1990, Cole et al. 2000) suggest that mice probably have a substantial
21 impact to the South Farallones invertebrate community, especially during the annual mouse
22 population boom of the late summer and fall. In New Zealand, researchers have estimated that
23 one house mouse would need to consume 4.4 g (0.16 oz) of invertebrate prey each day, if no
24 other foods were available, to meet its daily energy requirements (Miller 1999 as cited in Ruscoe
25 2001). Invertebrates perform numerous important ecosystem functions on the South Farallones
26 including pollination and decomposition, and they are a food resource for numerous species
27 including salamanders and migrating birds and bats. Consequently, mouse impacts to
28 invertebrates have the potential to reverberate throughout the South Farallones ecosystem.

29 30 4.4.3.3 Mouse impacts to marine foragers

31 32 4.4.3.3.1 Impacts to breeding seabirds

33
34 Non-native house mice are negatively affecting the populations of burrow- and crevice-nesting
35 seabirds on the South Farallones, particularly ashy and likely Leach's storm-petrels.

36
37 Mice are indirectly responsible for a substantial portion of ongoing declines in the breeding
38 populations of ashy storm-petrels, and likely Leach's storm-petrels, due to predation by
39 burrowing owls (PRBO unpubl. data). Burrowing owls are not considered island residents, but
40 each year migrating burrowing owls land on the South Farallones to rest. However, the South
41 Farallones' mouse population, which is at an annual peak during the fall, makes the Farallones
42 appear to be suitable hunting grounds for some of the burrowing owls that arrive in the fall. The
43 owls that choose to overwinter on the islands can survive on mice for the fall season and into the
44 early winter, but by mid-winter the mouse population has plummeted – the cyclical counterpart
45 to its fall peak. As a result, the overwintering burrowing owls are forced to find an alternative
46 food source, and they subsequently begin to prey on adult storm-petrels that arrive on the islands
47 in mid-winter to begin prospecting for nest sites and courtship. Predation by wintering owls

4. Environmental Consequences

1 accounts for substantial annual mortality in breeding ashy storm-petrels, estimated from counts
2 of bird remains near owl roosts at an average minimum of 67 ashy storm-petrels each year
3 (PRBO unpubl. data). There are other predatory landbirds that visit the South Farallones in
4 migration and winter, including other owl species, but none have had as noticeable an impact on
5 the local biota as the burrowing owl.

6
7 Most seabirds, and storm-petrels in particular,

- 8 • are long-lived – storm-petrels are known to live at least 35 years;
- 9 • mature slowly – storm-petrels generally do not begin breeding until they are 5 years old;
10 and
- 11 • have a low rate of reproduction – storm-petrel pairs almost always produce only one egg
12 per year (although they may lay a second egg if the first egg fails) and only 40-75 percent
13 breed successfully each year (Ainley and Boekelheide 1990, ~~PRBO unpubl. data~~, Ainley
14 1995).

15
16 These characteristics make each breeding adult storm-petrel especially valuable to the
17 reproductive success and survival of the species.

18
19 Researchers on the Farallones found that during a ~~recent~~ 20-year period, the population of
20 breeding adult ashy storm-petrels on the South Farallones decreased by about 42 percent
21 (Sydeman et al. 1998). Sydeman et al. identified owl predation, along with western gull
22 predation, egg and chick predation by mice, and long-term habitat changes as the major causes of
23 decline in the South Farallones ashy storm-petrel colony. While Sydeman et al. (1998)
24 speculated that burrowing owl predation was probably considerably less than gull predation,
25 more recent evidence (Mills 2006, PRBO unpubl. data) indicates that owl predation on storm-
26 petrels is higher than previously realized, although still less than predation rates by gulls. These
27 predation patterns are likely similar in Leach's storm-petrels, which are similar in size and
28 behavior to ashy storm-petrels. Leach's storm-petrels range throughout the North Pacific and
29 North Atlantic Oceans, and their population on the Farallones is small in comparison to other
30 Leach's storm-petrel colonies, but this colony appears to have declined substantially based on
31 mist net captures (PRBO unpubl. data; G. McChesney pers. comm.). Owl predation on Leach's
32 storm-petrels is likely contributing to the decline of the Farallones' Leach's storm-petrel
33 population.

34
35 In addition to their indirect impacts to storm-petrels, mice may also impact the birds directly.
36 Researchers have observed introduced house mice preying on seabird eggs and chicks on other
37 islands (see Cuthbert and Hilton 2004, Wanless et al. 2007, Angel et al. 2009), and there are a
38 few records of mouse predation on storm-petrel eggs and chicks on the South Farallones (Ainley
39 et al. 1990a). Mice likely also cause disturbance to storm-petrels as well as all the other crevice-
40 and burrow-nesting seabirds breeding on the islands by repeatedly entering their burrows,
41 possibly leading to abandonment of active or potential breeding sites.

43 4.4.3.3.2 Impacts to California brown pelican

44

4. Environmental Consequences

~~1 Mice are not known to affect the California brown pelican. Pelicans roosting on the South
2 Farallones would not be affected if the No Action alternative is adopted and mice are allowed to
3 remain.~~

4.4.3.3 Impacts to Steller sea lion

Mice are not known to affect Steller sea lions. Steller sea lions on and around the South Farallones would not be affected if the No Action alternative is adopted and mice are allowed to remain.

4.4.3.3.3 Impacts to pinnipeds

Mice are not known to affect pinnipeds on the South Farallones. Pinnipeds would not be affected if the No Action alternative is adopted and mice are allowed to remain.

4.4.3.4 Mouse impacts to vegetation

The endemic plants of the Farallones have evolved with no pressure from rodents and mice are thus a potential threat to native plants. Seeds of the endemic maritime goldfields, in particular, are a common food item for mice on the South Farallones (Jones and Golightly 2006).

On the other hand, many of the non-native plants that have been introduced to the South Farallones originally evolved under grazing pressure from small mammals such as rodents on the mainland, so mice are less likely to negatively affect them in their adopted island habitat. Particularly during the fall, mice on the Farallones commonly consume the seeds of the non-native *hare barely*, which has spread to new areas on the islands in recent years (Coulter and Irwin 2005). The Service currently recognizes non-native plants as a major threat to the South Farallones ecosystem. The presence of mice increases the likelihood that introduced plants that have an adaptation to dispersal by rodents will successfully establish and spread on the islands.

4.4.4 Impacts of Action Alternatives on Biological Resources

4.4.4.1 Impacts to Biological Resources vulnerable to toxicant use

4.4.4.1.1 Analysis framework for impacts from toxicant use

The risk of impacts from brodifacoum or any other rodenticide to individual animals is determined by 2 factors:

- The toxicity of the compound to that individual; and
- The likelihood that exposure to the compound will result in harm to that individual (Erickson and Urban 2004b).

From the perspective of risks from the rodenticide, the 3 action alternatives differ in both factors in terms of the individual species likelihood of exposure to the toxicant.

4.4.4.1.2 Toxicity

4. Environmental Consequences

1 *Toxicity to birds and mammals* – The toxicity of a particular compound to an individual animal is
2 often expressed in a value known as the “LD₅₀” – the dosage (D) of a toxicant that is lethal (L) to
3 50 percent of animals in a laboratory test. The EPA has compiled laboratory data for both
4 diphacinone and brodifacoum LD₅₀ values for a number of species. However, due to the
5 difficulty and expense of obtaining extensive laboratory data, the LD₅₀ values for many species,
6 including most species on the Farallones, remain unknown for brodifacoum. Besides lethal
7 toxicity, there are other physiological effects from ingestion of anticoagulants. Erickson and
8 Urban (2004b) report that individual birds and mammals that are exposed to anticoagulants and
9 survive may nevertheless experience internal hemorrhaging, external bleeding, and other
10 physical symptoms of anticoagulant toxicity.

11
12 The EPA has determined that the toxicity of brodifacoum to all birds, and mammals in general is
13 high and only requires one **dose** to be lethal (Erickson and Urban 2004b). Furthermore, animals
14 that have a large body mass, such as pinnipeds or cetaceans, would generally need to ingest
15 much more of the compound in order to reach an LD₅₀ threshold.

16
17 While the concentration of brodifacoum in bait pellets would be consistent, the number of bait
18 pellets that individual animals would need to consume would vary considerably and
19 unpredictably. Furthermore, predators and scavengers can also be exposed to a toxicant through
20 secondary or tertiary pathways by consuming individuals that were previously exposed to the
21 toxicant. It is difficult to predict the amount of toxicant that would be present in these prey
22 animals, and difficult to predict how much a particular predator or scavenger would need to
23 consume to reach a toxic threshold.

24
25 Overall, it is difficult to accurately predict risk to birds or mammals based on toxicity data.
26 Instead, risks from the toxicant will be estimated using the animals’ risk of exposure. However,
27 the large body mass of animals such as cetaceans, which would likely reduce the risk of toxic
28 effects, will also be taken into account. Additionally, we will assume a worst case scenario to
29 avoid underestimating the number of individuals that will be negatively impacted from
30 brodifacoum.

31 32 4.4.4.1.3 Toxicant Exposure

33
34 Exposures to toxicants are primarily dependent on 2 factors:

- 35 • Food habits, behavior patterns, and other specific characteristics that increase or decrease
36 an animal’s exposure to the toxicant; and
- 37 • The availability of the toxicant in the local environment.

38
39 The toxicant form used for rodent eradication can only effectively be delivered through oral
40 ingestion; animals can either ingest the toxicant by consuming bait pellets (known as “primary
41 exposure”), or by preying or scavenging on other animals that previously consumed bait pellets
42 (known as “secondary exposure”). Brodifacoum molecules adhere strongly to the bait pellet
43 grains and are unlikely to be leached away in moisture or precipitation. Once the pellets
44 disintegrate into particles that are too small for most foraging animals to consume, the toxicant is
45 essentially unavailable within the environment. Eventually, even the sub-measurable
46 concentrations of the toxicant remaining from a fully disintegrated pellet would break down into

4. Environmental Consequences

1 non-toxic compounds including carbon dioxide and water with no toxic intermediate compounds
2 (NPS 2000).

3
4 *Primary exposure* – Herbivorous and omnivorous species are much more likely to consume bait
5 (primary exposure) than carnivorous species (including insectivores) because the bait is
6 composed primarily of grain. None of the carnivorous or insectivorous species on the Farallones
7 would consume bait pellets intentionally as food; however, many insectivorous species will
8 likely consume bait while foraging for insects.

9
10 *Secondary exposure* – Mice and other animals that directly consume bait can also transfer some
11 of the toxicant in their systems to predators or scavengers through secondary exposure. Different
12 organisms show considerable variation in the amount of time that they retain toxicants in their
13 bodies. For vertebrates that are exposed sub-lethally, brodifacoum can be retained in the liver for
14 many months. Rats dosed sub-lethally had brodifacoum concentrations in their liver, which took
15 350 days to be reduced by 50 percent (Erickson and Urban 2004b). Brodifacoum retention times
16 for most bird species have not yet been determined. For invertebrates, the exact mechanisms of
17 brodifacoum retention are unclear but the general understanding is that most invertebrates only
18 retain brodifacoum briefly in their digestive system and not in body tissues (Booth et al. 2001).

19
20 At the Farallones, only a few species are at risk of exposure to the applied rodenticide through a
21 secondary pathway. Mice may be at risk of secondary exposure by consuming ~~crabs and other~~
22 invertebrates like crickets, dead ~~shore~~birds, and other mice that had previously consumed bait.
23 Shorebirds may be at risk of secondary exposure to rodenticide through the consumption of
24 invertebrates that had previously consumed bait. The salamander species at the Farallones may
25 be at risk of secondary exposure to rodenticide through the consumption of invertebrates that had
26 previously consumed bait.

28 4.4.4.2 Analysis framework for impacts from disturbance

30 *Helicopter operations*

31 The operation of low-flying aircraft throughout the Farallones would likely result in disturbance
32 to wildlife from sound, the sudden appearance of an aircraft, or a combination of both
33 (Efroymsen et al. 2001). Wildlife would be exposed to noises that exceed background levels.
34 Pinnipeds on the Farallones are most at risk from helicopter operations, which will be mitigated
35 by slowly approaching hauled out individuals to encourage them to leave the island directly
36 before the bait is applied. Due to the relatively low altitude at which helicopters would fly, the
37 majority of the helicopter noise would be focused in a narrow cone directly underneath them,
38 reducing the area of disturbance for each helicopter pass (Richardson et al. 1995). Animals on
39 shore would likely be exposed to higher-decibel noise than animals in the water; however,
40 ~~researchers at Grupo de Ecología y Conservación de Islas, A.C. (GECI) studied the impacts from~~
41 ~~helicopter operations to breeding boobies on Isla Isabel and found no significant effect to the~~
42 ~~birds (GECI video).~~ We do not anticipate that helicopter operations in association with the action
43 alternatives would cause more than a nominal disturbance to wildlife at the Farallones.

44
45 During each aerial bait application, all points on the Farallones will most likely be subject to 2
46 helicopter passes. Over the course of bait application operations, which may entail 2 pulses, there

4. Environmental Consequences

1 will likely be fewer than 10 days during which the helicopter would operate. The responses of
2 animals to aircraft disturbance and the adverse effects of this disturbance vary considerably
3 between species and different seasons.

4 *Personnel activities*

6 Additional wildlife disturbance could result from personnel traveling by foot across the island
7 (e.g., when hand-broadcasting bait, tending bait stations, and surveying for non-target mortality),
8 or traveling in small boats in the nearshore waters. Personnel dedicated to mouse eradication will
9 be based at the Farallones for around one month under Alternative B, and D, ~~and for up to 2~~
10 ~~years under Alternatives C.~~ Following eradication, there will be several monitoring visits to the
11 island for at least 2 years post eradication. There are personnel on the Farallones conducting
12 ongoing research, monitoring, and other management activities year-round, but mouse
13 eradication will increase the number of personnel and the extent of affect to species on the
14 island. Most current monitoring activities take place in discrete and limited areas of the island,
15 whereas mouse eradication operations will require personnel to travel throughout the island.
16 Personnel would be briefed on techniques to reduce wildlife disturbance, but disturbance events
17 will likely still occur.

Comment [g104]: Is this still true?

19 4.4.4.3 Affect Indices

20 The following impacts analysis identifies the level of risk from the perspective of bait
21 availability (the amount of time bait will be available through either primary or secondary
22 exposure pathways), risk of mortality from toxicant use (the toxicity of the toxicant to different
23 species based on toxicological properties), toxicant exposure risk level (the number of exposure
24 pathways available to individual species based on feeding ecology and toxicant fate), disturbance
25 risk (the sensitivity to disturbance and the amount of disturbance risk that individuals may be
26 exposed to during operations), extent of the risk within the population (the number of individuals
27 that may be affected from toxicant or disturbance and the affect that they will have to the global
28 or regional breeding population), and the duration of the risk (the period of time that individuals
29 will be exposed to toxicant or disturbance risks). The following indices illustrate the
30 methodology employed to analyze the impacts to each of the identified species for the 5 action
31 alternatives:

- 33 • Bait availability
 - 34 ○ Short: Bait or animal tissue with toxicant residue available for up to 26 days
 - 35 ○ Medium: Bait in animal tissue available for 37 – 90 days
 - 36 ○ Long: Toxicant persistent anywhere in the environment for more than 90 days
- 37 • Risk of mortality from toxicant use
 - 38 ○ None: No toxicological sensitivity
 - 39 ○ Low: Minor toxicological sensitivity
 - 40 ○ Medium: Moderate toxicological sensitivity
 - 41 ○ High: Severe toxicological sensitivity
- 42 • Toxicant exposure risk level
 - 43 ○ None: No exposure pathway
 - 44 ○ Low: Possible exposure pathway
 - 45 ○ Medium: One exposure pathway
 - 46 ○ High: Multiple exposure pathways

4. Environmental Consequences

- 1 • Disturbance risk
 - 2 ○ None: No disturbance pathway
 - 3 ○ Low: Low sensitivity to disturbance
 - 4 ○ Medium: Moderate sensitivity to disturbance
 - 5 ○ High: Severe sensitivity to disturbance
- 6 • Extent of toxicant/disturbance risk within a population
 - 7 ○ Individuals: Few individuals affected
 - 8 ○ Island population: Many individuals affected with no affect to the global or
 - 9 regional breeding population
 - 10 ○ Global or regional population: Many individuals affected with impacts to the
 - 11 global or regional breeding population
- 12 • Duration of the risk of the toxicant or from disturbance
 - 13 ○ Short: Impacts for up to 2 months
 - 14 ○ Medium: Impacts for more than 2 months and up to 6 months
 - 15 ○ Long: Impacts for more than 6 months

4.4.4.4 Impacts of Alternative B on Biological Resources: Aerial Brodifacoum

4.4.4.4.1 Impacts on Birds

20 Generally, birds that primarily eat plant matter such as seeds and fruits would initially be at high
21 risk for primary exposure to brodifacoum. Predators and scavengers would in some cases be at
22 high risk of secondary exposure to brodifacoum. Animals that feed on mice, mouse carcasses, or
23 large ground-dwelling invertebrates such as crickets would initially be at high risk of secondary
24 exposure to brodifacoum. Birds that have a broad, omnivorous diet would initially be at high risk
25 for both primary and secondary exposure.

26 The risk of exposure (either primary or secondary) in initially high-risk animals (terrestrial
27 herbivores, many predators and scavengers, and omnivores) would begin to decline rapidly
28 within 30 days of the final bait application session as the mouse population declines, bait pellets
29 are consumed or disintegrated, and bait becomes less available to invertebrate consumers. The
30 risk of exposure in these initially high-risk animals would generally be low within 30 days of the
31 final bait application and negligible within a few months thereafter.

32 On the other hand, birds foraging in the intertidal zone would be at lower risk for primary
33 exposure because pellets that drift into the water would disintegrate and become unavailable
34 within a few hours. Similarly, birds that forage primarily in the intertidal zone and specialize in
35 intertidal invertebrates would initially be at a low risk of secondary exposure. Also, birds that
36 feed primarily on flying insects and “micro-invertebrates” would be at an initially low risk of
37 secondary exposure due to the low likelihood that these classes of invertebrates would be
38 carrying brodifacoum in their systems; this risk would steadily decline to negligible within a few
39 months. The likelihood of exposure in intertidal specialists would decline even more rapidly,
40 becoming negligible within 30 days of the final bait application.

41 The following is a breakdown of the direct toxicant and disturbance impacts to each of the
42 identified bird species that are likely to be exposed to brodifacoum during the implementation of
43 Alternative B on the South Farallone Islands. Additionally, we have quantified the number of
44 individuals per species that are likely to be adversely affected by Alternative B by assuming the
45 worst case scenario and considering any individuals that may be present on the island during the
46 eradication operations to be vulnerable to adverse impacts from this action alternative:

Comment [g105]: Please review impacts analysis for alternative B; after the methodology is approved we will add in the analysis for alternatives C and D.

4. Environmental Consequences

Raptors:

Ferruginous Hawk, Red-tailed Hawk, Sharp-shinned Hawk

Toxicant risk

Ferruginous, Red-tailed, and Sharp-shinned hawks would be exposed to brodifacoum through secondary exposure pathways by consuming other species that have been exposed to the toxicant. Generally, Ferruginous, Red-tailed, and Sharp-shinned Hawks consume small mammals, small birds, reptiles, and insects. Based off of the their feeding habits the bait availability for these hawks would be for the medium-term, the risk of mortality from toxicant use would be high, and the toxicant exposure risk is high due to the range of secondary toxicant exposure pathways. The duration of the risk will likely be for the medium-term due to the retention time of the toxicant in the tissue of species that provide a secondary exposure pathway to hawks. The extent of the affect will be to the few individuals that are seen at this time on the island.

Disturbance risk

Ferruginous, Red-tailed, and Sharp-shinned Hawks would be exposed to disturbances from both ground and air operations, which will likely cause them to flush the area to an alternate site on the island. The impacts associated with disturbance risks for this alternative is low, the duration of the disturbance will be for the short-term, and the extent of the affect will be to the few individuals that are seen at this time on the island.

- XXX individuals are likely to be exposed to impacts from alternative B.

Rough-legged Hawk

Toxicant risk

Rough-legged Hawks would be exposed to brodifacoum through secondary exposure pathways by consuming other species that have been exposed to the toxicant. Generally, Rough-legged Hawks consume small mammals, small birds, carrion (animal carcasses), and insects. Based off of the their feeding habits the bait availability for these hawks would be for the medium-term, the risk of mortality from toxicant use would be high, and the toxicant exposure risk is high due to the range of secondary toxicant exposure pathways. The duration of the risk will likely be for the medium-term due to the retention time of the toxicant in the tissue of species that provide a secondary exposure pathway to hawks. The extent of the affect will be to the few individuals that are seen at this time on the island.

Disturbance risk

Rough-legged Hawks would be exposed to disturbances from both ground and air operations, which will likely cause them to flush the area to an alternate site on the island. The impacts associated with disturbance risks for this alternative is low, the duration of the disturbance will be for the short-term, and the extent of the affect will be to the few individuals that are seen at this time on the island.

- XXX individuals are likely to be exposed to impacts from alternative B.

Northern Harrier Hawk

4. Environmental Consequences

1 **Toxicant risk**

2 Northern Harrier **Hawks** would be exposed to brodifacoum through secondary exposure
3 pathways by consuming other species that have been exposed to the toxicant. Generally,
4 Northern Harrier **Hawks** consume small mammals, small birds, **carrion**, reptiles, and insects.
5 Based off of the their feeding habits the bait availability for these hawks would be for the
6 medium-term, the risk of mortality from toxicant use would be high, and the toxicant exposure
7 risk is high due to the range of secondary toxicant exposure pathways. The duration of the risk
8 will likely be for the medium-term due to the retention time of the toxicant in the tissue of
9 species that provide a secondary exposure pathway to hawks. The extent of the affect will be to
10 the few individuals that are seen at this time on the island.

11 **Disturbance risk**

12 Northern Harrier **Hawks** would be exposed to disturbances from both ground and air operations,
13 which will likely cause them to flush the area to an alternate site on the island. The impacts
14 associated with disturbance risks for this alternative is low, the duration of the disturbance will
15 be for the short-term, and the extent of the affect will be to the few individuals that are seen at
16 this time on the island.

- 17 • XXX individuals are likely to be exposed to impacts from alternative B.

18

19 **Cooper's Hawk**

20 **Toxicant risk**

21 Cooper's Hawks would be exposed to brodifacoum through secondary exposure pathways by
22 consuming other species that have been exposed to the toxicant. Generally, Cooper's Hawks
23 consume small mammals, small birds, and sometimes reptiles. Based off of the their feeding
24 habits the bait availability for these hawks would be for the medium-term, the risk of mortality
25 from toxicant use would be high, and the toxicant exposure risk is high due to the range of
26 secondary toxicant exposure pathways. The duration of the risk will likely be for the medium-
27 term due to the retention time of the toxicant in the tissue of species that provide a secondary
28 exposure pathway to hawks. The extent of the affect will be to the few individuals that are seen
29 at this time on the island.

30 **Disturbance risk**

31 Cooper's Hawks would be exposed to disturbances from both ground and air operations, which
32 will likely cause them to flush the area to an alternate site on the island. The impacts associated
33 with disturbance risks for this alternative is low, the duration of the disturbance will be for the
34 short-term, and the extent of the affect will be to the few individuals that are seen at this time on
35 the island.

- 36 • XXX individuals are likely to be exposed to impacts from alternative B.

37

38 **Merlin, Short-eared Owl, and American Kestrel**

39 **Toxicant risk**

40 Merlins, Short-eared Owls, and American Kestrels would be exposed to brodifacoum through
41 secondary exposure pathways by consuming other species that have been exposed to the
42 toxicant. Generally, these species consume small mammals, small birds, and insects. Based off
43 of the their feeding habits the bait availability for these species would be for the medium-term,

4. Environmental Consequences

1 the risk of mortality from toxicant use would be high, and the toxicant exposure risk is high due
2 to the range of secondary toxicant exposure pathways. The duration of the risk will likely be for
3 the medium-term due to the retention time of the toxicant in the tissue of species that provide a
4 secondary exposure pathway to these raptors. The extent of the affect will be to the few
5 individuals that are seen at this time on the island.

6 ***Disturbance risk***

7 Merlins, Short-eared Owls, and American Kestrels would be exposed to disturbances from both
8 ground and air operations, which will likely cause them to flush the area to an alternate site on
9 the island. The impacts associated with disturbance risks for this alternative is low, the duration
10 of the disturbance will be for the short-term, and the extent of the affect will be to the few
11 individuals that are seen at this time on the island.

- 12 • XXX individuals are likely to be exposed to impacts from alternative B.

13

14 **Long-eared Owls and Barn Owls**

15 ***Toxicant risk***

16 Long-eared and Barn Owls would be exposed to brodifacoum through secondary exposure
17 pathways by consuming other species that have been exposed to the toxicant. Generally, Long-
18 eared and Barn Owls consume small mammals, small birds, reptiles, and insects. Based off of
19 the their feeding habits the bait availability for these owls would be for the medium-term, the
20 risk of mortality from toxicant use would be high, and the toxicant exposure risk is high due to
21 the range of secondary toxicant exposure pathways. The duration of the risk will likely be for the
22 medium-term due to the retention time of the toxicant in the tissue of species that provide a
23 secondary exposure pathway to these raptors. The extent of the affect will be to the few
24 individuals that are seen at this time on the island.

25 ***Disturbance risk***

26 Long-eared and Barn Owls would be exposed to disturbances from both ground and air
27 operations, which will likely cause them to flush the area to an alternate site on the island. The
28 impacts associated with disturbance risks for this alternative is low, the duration of the
29 disturbance will be for the short-term, and the extent of the affect will be to the few individuals
30 that are seen at this time on the island.

- 31 • XXX individuals are likely to be exposed to impacts from alternative B.

32

33 **Northern Saw-whet Owl**

34 ***Toxicant risk***

35 Northern Saw-whet Owls would be exposed to brodifacoum through secondary exposure
36 pathways by consuming other species that have been exposed to the toxicant. Generally,
37 Northern Saw-whet Owls consume small mammals, and some insects. Based off of the their
38 feeding habits the bait availability for these owls would be for the medium-term, the risk of
39 mortality from toxicant use would be high, and the toxicant exposure risk is high due to the range
40 of secondary toxicant exposure pathways. The duration of the risk will likely be for the medium-
41 term due to the retention time of the toxicant in the tissue of species that provide a secondary
42 exposure pathway to owls. The extent of the affect will be to the few individuals that are seen at
43 this time on the island.

4. Environmental Consequences

Disturbance risk

Northern Saw-whet Owls would be exposed to disturbances from both ground and air operations, which will likely cause them to flush the area to an alternate site on the island. The impacts associated with disturbance risks for this alternative is low, the duration of the disturbance will be for the short-term, and the extent of the affect will be to the few individuals that are seen at this time on the island.

- XXX individuals are likely to be exposed to impacts from alternative B.

White-tailed Kite

Toxicant risk

White-tailed Kites would be exposed to brodifacoum through secondary exposure pathways by consuming other species that have been exposed to the toxicant. Generally, White-tailed Kites only consume small mammals. Based off of the their feeding habits the bait availability for kites would be for the medium-term, the risk of mortality from toxicant use would be high, and the toxicant exposure risk is medium due to the single toxicant exposure pathway. The duration of the risk will likely be for the medium-term due to the retention time of the toxicant in the tissue of species that provide a secondary exposure pathway to kites. The extent of the affect will be to the few individuals that are seen at this time on the island.

Disturbance risk

White-tailed Kites would be exposed to disturbances from both ground and air operations, which will likely cause them to flush the area to an alternate site on the island. The impacts associated with disturbance risks for this alternative is low, the duration of the disturbance will be for the short-term, and the extent of the affect will be to the few individuals that are seen at this time on the island.

- XXX individuals are likely to be exposed to impacts from alternative B.

Bird Species Intended for Mitigation:

Burrowing Owls

Toxicant risk

Burrowing Owls that remain on the island or arrive after they are captured and removed for eradication operations would be exposed to brodifacoum through secondary exposure pathways by consuming other species that have been exposed to the toxicant. Generally, Burrowing Owls consume small mammals, small birds, reptiles, and insects. Based off of the their feeding habits the bait availability for these owls would be for the medium-term, the risk of mortality from toxicant use would be high, and the toxicant exposure risk is high due to the range of secondary toxicant exposure pathways. The duration of the risk will likely be for the medium-term due to the retention time of the toxicant in the tissue of species that provide a secondary exposure pathway to owls. The extent of the affect will be to the individuals that remain on the island after the eradication team captures and removes as many individuals as possible

4. Environmental Consequences

Disturbance risk

Burrowing Owls that remain on the island during eradication operations would be exposed to disturbances from both ground and air operations, which will likely cause them to flush the area to an alternate site on the island. The impacts associated with disturbance risks for this alternative is low, the duration of the disturbance will be for the short-term, and the extent of the affect will be to the few individuals that are seen at this time on the island. However, owls that are captured and taken into captivity will experience a high disturbance risk, the extent of the affect will be to the individuals taken into captivity, and the duration will be for the medium term to ensure that they are not released back to the Farallones while the toxicant exposure risk is still high.

- XXX individuals are likely to be exposed to impacts from alternative B.

Peregrine Falcon

Toxicant risk

Peregrine Falcons that remain on the island or arrive after they are captured and removed for eradication operations would be exposed to brodifacoum through secondary exposure pathways by consuming other species that have been exposed to the toxicant. Generally, Peregrine Falcons consume ~~doves, shorebirds, waterfowl, and passerines~~. Based off of their feeding habits the bait availability for these falcons would be for the medium-term, the risk of mortality from toxicant use would be high, and the toxicant exposure risk is high due to the range of secondary toxicant exposure pathways. The duration of the risk will likely be for the medium-term due to the retention time of the toxicant in the tissue of species that provide a secondary exposure pathway to falcons. The extent of the affect will be to the few individuals that are seen at this time on the island.

Disturbance risk

Peregrine Falcons that remain on the island during eradication operations would be exposed to disturbances from both ground and air operations, which will likely cause them to flush the area to an alternate site on the island. The impacts associated with disturbance risks for this alternative is low, the duration of the disturbance will be for the short-term, and the extent of the affect will be to the few individuals that are seen at this time on the island. However, ~~owls~~ that are captured and taken into captivity will experience a high disturbance risk, the extent of the affect will be to the individuals taken into captivity, and the duration will be for the medium term to ensure that they are not released back to the Farallones while the toxicant exposure risk is still high.

Common Raven

Toxicant risk

Common Ravens that remain on the island or arrive after they are captured and removed for eradication operations would be exposed to brodifacoum through secondary exposure pathways by consuming other species that have been exposed to the toxicant. Ravens are omnivorous and consume marine and other invertebrates, carrion, ~~bird eggs~~, fruit, and seeds. Based off of their feeding habits the bait availability for ravens would be for the medium-term, the risk of mortality from toxicant use would be high, and the toxicant exposure risk is high due to the range of secondary toxicant exposure pathways. The duration of the risk will likely be for the medium-term due to the retention time of the toxicant in the tissue of species that provide a secondary

4. Environmental Consequences

1 exposure pathway to ravens. The extent of the affect will be to the few individuals that are seen
2 at this time on the island.

3 ***Disturbance risk***

4 Peregrine Falcons that remain on the island during eradication operations would be exposed to
5 disturbances from both ground and air operations, which will likely cause them to flush the area
6 to an alternate site on the island. The impacts associated with disturbance risks for this
7 alternative is low, the duration of the disturbance will be for the short-term, and the extent of the
8 affect will be to the few individuals that are seen at this time on the island. However, owls that
9 are captured and taken into captivity will experience a high disturbance risk, the extent of the
10 affect will be to the individuals taken into captivity, and the duration will be for the medium term
11 to ensure that they are not released back to the Farallones while the toxicant exposure risk is still
12 high.

- 13 • XXX individuals are likely to be exposed to impacts from alternative B.

14 Songbirds:

15 **Hermit Thrush, Cedar Waxwing, and American Robin**

16 ***Toxicant risk***

17 Hermit Thrushes, Cedar Waxwings, and American Robins would be exposed to brodifacoum
18 through secondary exposure pathways by consuming other species that have been exposed to the
19 toxicant. Hermit Thrushes, Cedar Waxwings, and American Robins consume fruit, insects, and
20 **intertidal invertebrates**. Based off of their feeding habits the bait availability for these
21 songbirds would be for the medium-term, the risk of mortality from toxicant use would be high,
22 and the toxicant exposure risk is high due to the range of secondary toxicant exposure pathways.
23 The duration of the risk will likely be for the medium-term due to the retention time of the
24 toxicant in the tissue of species that provide a secondary exposure pathway to songbirds. The
25 extent of the affect will be to the few individuals that are seen at this time on the island.
26
27

28 ***Disturbance risk***

29 Hermit Thrushes, Cedar Waxwings, and American Robins would be exposed to disturbances
30 from both ground and air operations, which will likely cause them to flush the area to an
31 alternate site on the island. The impacts associated with disturbance risks for this alternative is
32 low, the duration of the disturbance will be for the short-term, and the extent of the affect will be
33 to the few individuals that are seen at this time on the island.

- 34 • XXX individuals are likely to be exposed to impacts from alternative B.

35 **European Starling**

36 ***Toxicant risk***

37 European Starlings would be exposed to brodifacoum through primary and secondary exposure
38 pathways by either directly consuming bait (primary) or consuming other species that have been
39 exposed to the toxicant (secondary). Starlings consume fruit, insects, and seeds. Based off of the
40 their feeding habits the bait availability for these songbirds would be for the medium-term, the
41 risk of mortality from toxicant use would be high, and the toxicant exposure risk is high due to
42 the range of secondary toxicant exposure pathways. The duration of the risk will likely be for the
43

4. Environmental Consequences

1 medium-term due to the retention time of the toxicant in the tissue of species that provide a
2 secondary exposure pathway to starlings. The extent of the affect will be to the few individuals
3 that are seen at this time on the island.

4 ***Disturbance risk***

5 European Starlings would be exposed to disturbances from both ground and air operations,
6 which will likely cause them to flush the area to an alternate site on the island. The impacts
7 associated with disturbance risks for this alternative are medium, the duration of the disturbance
8 will be for the short-term, and the extent of the affect will be to the few individuals that are seen
9 at this time on the island.

- 10 • XXX individuals are likely to be exposed to impacts from alternative B.

12 **Varied Thrush**

13 ***Toxicant risk***

14 Varied Thrushes would be exposed to brodifacoum through primary and secondary exposure
15 pathways by either directly consuming bait (primary) or consuming other species that have been
16 exposed to the toxicant (secondary). Varied Thrushes consume fruit, invertebrates, ~~acorns~~, and
17 seeds. Based off of the their feeding habits the bait availability for these songbirds would be for
18 the medium-term, the risk of mortality from toxicant use would be high, and the toxicant
19 exposure risk is high due to the range of secondary toxicant exposure pathways. The duration of
20 the risk will likely be for the medium-term due to the retention time of the toxicant in the tissue
21 of species that provide a secondary exposure pathway to starlings. The extent of the affect will
22 be to the few individuals that are seen at this time on the island.

23 ***Disturbance risk***

24 European Starlings would be exposed to disturbances from both ground and air operations,
25 which will likely cause them to flush the area to an alternate site on the island. The impacts
26 associated with disturbance risks for this alternative are medium, the duration of the disturbance
27 will be for the short-term, and the extent of the affect will be to the few individuals that are seen
28 at this time on the island.

- 29 • XXX individuals are likely to be exposed to impacts from alternative B.

31 **American Pipit**

32 ***Toxicant risk***

33 American Pipit would be exposed to brodifacoum through primary and secondary exposure
34 pathways by either directly consuming bait (primary) or consuming other species that have been
35 exposed to the toxicant (secondary). Pipits consume invertebrates, and seeds. Based off of the
36 their feeding habits the bait availability for these songbirds would be for the medium-term, the
37 risk of mortality from toxicant use would be high, and the toxicant exposure risk is high due to
38 the range of secondary toxicant exposure pathways. The duration of the risk will likely be for the
39 medium-term due to the retention time of the toxicant in the tissue of species that provide a
40 secondary exposure pathway to pipits. The extent of the affect will be to the few individuals that
41 are seen at this time on the island.

4. Environmental Consequences

1 ***Disturbance risk***

2 American Pipit would be exposed to disturbances from both ground and air operations, which
3 will likely cause them to flush the area to an alternate site on the island. The impacts associated
4 with disturbance risks for this alternative are medium, the duration of the disturbance will be for
5 the short-term, and the extent of the affect will be to the few individuals that are seen at this time
6 on the island.

- 7 • XXX individuals are likely to be exposed to impacts from alternative B.
8

9 **Black Phoebe**

10 ***Toxicant risk***

11 Black Phoebes would be exposed to brodifacoum through secondary exposure pathways by
12 consuming other species that have been exposed to the toxicant. Phoebes consume insects and
13 fish. Based off of the their feeding habits the bait availability for these songbirds would be for
14 the medium-term, the risk of mortality from toxicant use would be high, and the toxicant
15 exposure risk is high due to the range of secondary toxicant exposure pathways. The duration of
16 the risk will likely be for the medium-term due to the retention time of the toxicant in the tissue
17 of species that provide a secondary exposure pathway to phoebes. The extent of the affect will be
18 to the few individuals that are seen at this time on the island.

19 ***Disturbance risk***

20 Black Phoebes would be exposed to disturbances from both ground and air operations, which
21 will likely cause them to flush the area to an alternate site on the island. The impacts associated
22 with disturbance risks for this alternative are medium, the duration of the disturbance will be for
23 the short-term, and the extent of the affect will be to the few individuals that are seen at this time
24 on the island.

- 25 • XXX individuals are likely to be exposed to impacts from alternative B.

26 *Insectivores:*

27

28 **Yellow-rumped Warbler**

29 ***Toxicant risk***

30 Yellow-rumped Warbler would be exposed to brodifacoum through secondary exposure
31 pathways by consuming other species that have been exposed to the toxicant. Yellow-rumped
32 Warblers consume fruit, insects, and intertidal invertebrates. Based off of the their feeding
33 habits the bait availability for these insectivores would be for the medium-term, the risk of
34 mortality from toxicant use would be high, and the toxicant exposure risk is high due to the range
35 of secondary toxicant exposure pathways. The duration of the risk will likely be for the medium-
36 term due to the retention time of the toxicant in the tissue of species that provide a secondary
37 exposure pathway to insectivores. The extent of the affect will be to the few individuals that are
38 seen at this time on the island.

39 ***Disturbance risk***

40 Yellow-rumped warbler would be exposed to disturbances from both ground and air operations,
41 which will likely cause them to flush the area to an alternate site on the island. The impacts
42 associated with disturbance risks for this alternative is low, the duration of the disturbance will

4. Environmental Consequences

1 be for the short-term, and the extent of the affect will be to the few individuals that are seen at
2 this time on the island.

- 3 • XXX individuals are likely to be exposed to impacts from alternative B.

4 **Golden-crowned Kinglet, Ruby-crowned Kinglet, and Western Palm Warbler**

6 ***Toxicant risk***

7 Golden-crowned Kinglets, Ruby-crowned Kinglet, and Western Palm Warblers would be
8 exposed to brodifacoum through primary and secondary exposure pathways by either directly
9 consuming bait (primary) or consuming other species that have been exposed to the toxicant
10 (secondary). These insectivores consume insects, fruit, and seeds. Based off of the their feeding
11 habits the bait availability for these insectivores would be for the medium-term, the risk of
12 mortality from toxicant use would be high, and the toxicant exposure risk is high due to the range
13 of secondary toxicant exposure pathways. The duration of the risk will likely be for the medium-
14 term due to the retention time of the toxicant in the tissue of species that provide a secondary
15 exposure pathway to these insectivores. The extent of the affect will be to the few individuals
16 that are seen at this time on the island.

17 ***Disturbance risk***

18 Golden-crowned Kinglets, Ruby-crowned Kinglets, and Western Palm Warblers would be
19 exposed to disturbances from both ground and air operations, which will likely cause them to
20 flush the area to an alternate site on the island. The impacts associated with disturbance risks for
21 this alternative are medium, the duration of the disturbance will be for the short-term, and the
22 extent of the affect will be to the few individuals that are seen at this time on the island.

- 23 • XXX individuals are likely to be exposed to impacts from alternative B.

25 **Townsend's Warbler**

26 ***Toxicant risk***

27 Townsend's Warblers would be exposed to brodifacoum through primary and secondary
28 exposure pathways by either directly consuming bait (primary) or consuming other species that
29 have been exposed to the toxicant (secondary). Townsend's Warblers consume insects, and
30 seeds. Based off of the their feeding habits the bait availability for these songbirds would be for
31 the medium-term, the risk of mortality from toxicant use would be high, and the toxicant
32 exposure risk is high due to the range of secondary toxicant exposure pathways. The duration of
33 the risk will likely be for the medium-term due to the retention time of the toxicant in the tissue
34 of species that provide a secondary exposure pathway to these warblers. The extent of the affect
35 will be to the few individuals that are seen at this time on the island.

36 ***Disturbance risk***

37 Townsend's Warblers would be exposed to disturbances from both ground and air operations,
38 which will likely cause them to flush the area to an alternate site on the island. The impacts
39 associated with disturbance risks for this alternative are medium, the duration of the disturbance
40 will be for the short-term, and the extent of the affect will be to the few individuals that are seen
41 at this time on the island.

- 42 • XXX individuals are likely to be exposed to impacts from alternative B.

4. Environmental Consequences

Resident Sparrows:

Fox Sparrow, White-crowned Sparrow, Golden-crowned Sparrow, Dark-eyed Junco, Western Meadowlark

Toxicant risk

Fox Sparrows, White-crowned Sparrows, Golden-crowned Sparrows, Dark-eyed Juncos, and Western Meadowlarks would be exposed to brodifacoum through primary and secondary exposure pathways by either directly consuming bait (primary) or consuming other species that have been exposed to the toxicant (secondary). These species primarily consume invertebrates and seeds. Based off of the their feeding habits the bait availability for these sparrows would be for the medium-term, the risk of mortality from toxicant use would be high, and the toxicant exposure risk is high due to the range of secondary toxicant exposure pathways. The duration of the risk will likely be for the medium-term due to the retention time of the toxicant in the tissue of species that provide a secondary exposure pathway to these sparrows. The extent of the affect will be to the island population.

Disturbance risk

Fox Sparrows, White-crowned Sparrows, Golden-crowned Sparrows, Dark-eyed Juncos, and Western Meadowlarks would be exposed to disturbances from both ground and air operations, which will likely cause them to flush the area to an alternate site on the island. The impacts associated with disturbance risks for this alternative are medium, the duration of the disturbance will be for the short-term, and the extent of the affect will be to the island population.

- XXX individuals are likely to be exposed to impacts from alternative B.

Non-resident Sparrows:

Chipping Sparrow, Spotted Towhee, Savannah Sparrow, White-throated Sparrow, Red-winged Blackbird, Brewer's Blackbird, Purple Finch, Pine Siskin, Lesser Goldfinch

Toxicant risk

Chipping Sparrows, Spotted Towhees, Savannah Sparrows, White-throated Sparrows, Red-winged Blackbird, Brewer's Blackbirds, Purple Finches, Pine Siskins, and Lesser Goldfinches would be exposed to brodifacoum through primary and secondary exposure pathways by either directly consuming bait (primary) or consuming other species that have been exposed to the toxicant (secondary). These species primarily consume invertebrates and seeds. Based off of the their feeding habits the bait availability for these sparrows would be for the medium-term, the risk of mortality from toxicant use would be high, and the toxicant exposure risk is high due to the range of secondary toxicant exposure pathways. The duration of the risk will likely be for the short-term because individuals will only present on the island for a very short period of time. The extent of the affect will be to the few individuals that will be on the island.

Disturbance risk

Chipping Sparrows, Spotted Towhees, Savannah Sparrows, White-throated Sparrows, Red-winged Blackbird, Brewer's Blackbirds, Purple Finches, Pine Siskins, and Lesser Goldfinches would be exposed to disturbances from both ground and air operations, which will likely cause them to flush the area to an alternate site on the island. The impacts associated with disturbance

4. Environmental Consequences

1 risks for this alternative are low, the duration of the disturbance will be for the short-term, and
2 the extent of the affect will be to the few individuals that are seen at this time on the island.

- 3 • XXX individuals are likely to be exposed to impacts from alternative B.

4 **Violet-green Swallow**

6 ***Toxicant risk***

7 Violet-green Swallows would be exposed to brodifacoum through secondary exposure pathways
8 by consuming insects that have been exposed to the toxicant. Based off of the their feeding
9 habits the bait availability for these songbirds would be for the medium-term, the risk of
10 mortality from toxicant use would be high, and the toxicant exposure risk is medium due to the
11 range of secondary toxicant exposure pathways. The duration of the risk will likely be for the
12 medium-term due to the retention time of the toxicant in the tissue of species that provide a
13 secondary exposure pathway to swallows. The extent of the affect will be to the few individuals
14 that are seen at this time on the island.

15 ***Disturbance risk***

16 Violet-green Swallows would be exposed to disturbances from both ground and air operations,
17 which will likely cause them to flush the area to an alternate site on the island. The impacts
18 associated with disturbance risks for this alternative is low, the duration of the disturbance will
19 be for the short-term, and the extent of the affect will be to the few individuals that are seen at
20 this time on the island.

- 21 • XXX individuals are likely to be exposed to impacts from alternative B

23 **Anna's Hummingbird**

24 ***Toxicant risk***

25 Anna's Hummingbirds would be exposed to brodifacoum through secondary exposure pathways
26 by consuming insects that have been exposed to the toxicant. Hummingbirds primarily consume
27 nectar, ~~however, they frequently consume insects while feeding.~~ Therefore, Based off of the
28 their feeding habits the bait availability for these hummingbirds would be for the medium-term,
29 the risk of mortality from toxicant use would be high, and the toxicant exposure risk is medium
30 due to the range of secondary toxicant exposure pathways. The duration of the risk will likely be
31 for the medium-term due to the retention time of the toxicant in the tissue of species that provide
32 a secondary exposure pathway to hummingbirds. The extent of the affect will be to the few
33 individuals that are seen at this time on the island.

34 ***Disturbance risk***

35 Anna's Hummingbirds would be exposed to disturbances from both ground and air operations,
36 which will likely cause them to flush the area to an alternate site on the island. The impacts
37 associated with disturbance risks for this alternative is low, the duration of the disturbance will
38 be for the short-term, and the extent of the affect will be to the few individuals that are seen at
39 this time on the island.

- 40 • XXX individuals are likely to be exposed to impacts from alternative B

42 **Shorebirds:**

4. Environmental Consequences

1 **Wandering Tattler and Black Turnstone**

2 ***Toxicant risk***

3 Wandering Tattlers and Black Turnstones would be exposed to brodifacoum through secondary
4 exposure pathways by consuming other species that have been exposed to the toxicant. Tattlers
5 and turnstones consume ~~insects and intertidal invertebrates~~. Based off of the their feeding habits
6 the bait availability for these shorebirds would be for the medium-term, the risk of mortality
7 from toxicant use would be high, and the toxicant exposure risk is **high** due to the range of
8 secondary toxicant exposure pathways. The duration of the risk will likely be for the medium-
9 term due to the retention time of the toxicant in the tissue of species that provide a secondary
10 exposure pathway to shorebirds. The extent of the affect will be to the few individuals that are
11 seen at this time on the island.

12 ***Disturbance risk***

13 Wandering Tattlers and Black Turnstones would be exposed to disturbances from both ground
14 and air operations, which will likely cause them to flush the area to an alternate site on the island.
15 The impacts associated with disturbance risks for this alternative are medium, the duration of the
16 disturbance will be for the short-term, and the extent of the affect will be to the few individuals
17 that are seen at this time on the island.

- 18 • XXX individuals are likely to be exposed to impacts from alternative B.

19 **Black Oystercatchers**

20 ***Toxicant risk***

21 Black Oystercatchers would be exposed to brodifacoum through secondary exposure pathways
22 by consuming other species that have been exposed to the toxicant. Oystercatchers consume
23 marine invertebrates and **fish**. Based off of the their feeding habits the bait availability for these
24 songbirds would be for the medium-term, the risk of mortality from toxicant use would be high,
25 and the toxicant exposure risk is **high** due to the range of secondary toxicant exposure pathways.
26 The duration of the risk will likely be for the medium-term due to the retention time of the
27 toxicant in the tissue of species that provide a secondary exposure pathway to Oystercatchers.
28 The extent of the affect will be to the few individuals that are seen at this time on the island.

29 ***Disturbance risk***

30 Black ~~Phoebes~~ would be exposed to disturbances from both ground and air operations, which
31 will likely cause them to flush the area to an alternate site on the island. The impacts associated
32 with disturbance risks for this alternative are medium, the duration of the disturbance will be for
33 the short-term, and the extent of the affect will be to the few individuals that are seen at this time
34 on the island.

- 35 • XXX individuals are likely to be exposed to impacts from alternative B.

36 **Whimbrel**

37 ***Toxicant risk***

38 Whimbrels would be exposed to brodifacoum through primary and secondary exposure pathways
39 by either directly consuming bait (primary) or consuming other species that have been exposed
40 to the toxicant (secondary). Whimbrels consume insects, and **seeds**. Based off of the their

4. Environmental Consequences

1 feeding habits the bait availability for these songbirds would be for the medium-term, the risk of
2 mortality from toxicant use would be high, and the toxicant exposure risk is high due to the range
3 of secondary toxicant exposure pathways. The duration of the risk will likely be for the medium-
4 term due to the retention time of the toxicant in the tissue of species that provide a secondary
5 exposure pathway to these shorebirds. The extent of the affect will be to the few individuals that
6 are seen at this time on the island.

7 ***Disturbance risk***

8 Whimbrels would be exposed to disturbances from both ground and air operations, which will
9 likely cause them to flush the area to an alternate site on the island. The impacts associated with
10 disturbance risks for this alternative are medium, the duration of the disturbance will be for the
11 short-term, and the extent of the affect will be to the few individuals that are seen at this time on
12 the island.

- 13 • XXX individuals are likely to be exposed to impacts from alternative B.

14 Seabirds:

15 **Western Gull**

16 ***Toxicant risk***

17 Western Gulls would be exposed to brodifacoum through primary and secondary exposure
18 pathways by either directly consuming bait (primary) or consuming other species that have been
19 exposed to the toxicant (secondary). Western Gulls are omnivorous and opportunistic feeders
20 consuming fish, aquatic invertebrates, birds, eggs, and carrion. Additionally, Western Gulls have been
21 documented eating rodenticide bait pellets on the Farallones and other islands in the region.
22 Based off of their feeding habits the bait availability for these gulls would be for the medium-
23 term, the risk of mortality from toxicant use would be high, and the toxicant exposure risk is high
24 due to the range of secondary toxicant exposure pathways. The duration of the risk will likely be
25 for the medium-term due to the retention time of the toxicant in the tissue of species that provide
26 a secondary exposure pathway to these gulls. The extent of the affect will be to the entire
27 Farallones Island population.

28 ***Disturbance risk***

29 Western Gulls would be exposed to disturbances from ground, air, and gull hazing operations.
30 Gull hazing will be used as a mitigation measure during aerial baiting operations to help
31 minimize the number of gulls that are likely to consume bait. The impacts associated with
32 disturbance risks for this alternative are high because gulls may be very sensitive to hazing
33 causing them to alter their feeding and roosting habits, disrupting their normal behavior. The
34 duration of the disturbance will be for the medium-term, and the extent of the affect will be to
35 the entire Farallones Island population.

- 36 • XXX individuals are likely to be exposed to impacts from alternative B.

37 **Ring-Billed Gull**

38 ***Toxicant risk***

39 Ring-billed Gulls would be exposed to brodifacoum through primary and secondary exposure
40 pathways by either directly consuming bait (primary) or consuming other species that have been
41

4. Environmental Consequences

1 exposed to the toxicant (secondary). Ring-billed Gulls are omnivorous and opportunistic feeders
2 consuming fish, insects, mice, and eggs. Additionally, Gulls have been known to eat rodenticide
3 bait islands in the region and around the world. Based off of the their feeding habits the bait
4 availability for these gulls would be for the medium-term, the risk of mortality from toxicant use
5 would be high, and the toxicant exposure risk is high due to the range of secondary toxicant
6 exposure pathways. The duration of the risk will likely be for the medium-term due to the
7 retention time of the toxicant in the tissue of species that provide a secondary exposure pathway
8 to these gulls. The extent of the affect will be to the entire Farallones Island population.

9 ***Disturbance risk***

10 Ring-billed Gulls would be exposed to disturbances from ground, air, and gull hazing operations.
11 Gull hazing will be used as a mitigation measure during aerial baiting operations to help
12 minimize the number of gulls that are likely to consume bait. The impacts associated with
13 disturbance risks for this alternative are high because gulls may be very sensitive to hazing
14 causing them to alter their feeding and roosting habits disruption their normal behavior. The
15 duration of the disturbance will be for the medium-term, and the extent of the affect will be to
16 the entire Farallones Island population.

- 17 • XXX individuals are likely to be exposed to impacts from alternative B.

18 19 **California Gull**

20 ***Toxicant risk***

21 California Gulls would be exposed to brodifacoum through primary and secondary exposure
22 pathways by either directly consuming bait (primary) or consuming other species that have been
23 exposed to the toxicant (secondary). California Gulls are omnivorous and opportunistic feeders
24 consuming invertebrates, mice, birds, eggs, and fish. Additionally, Gulls have been known to eat
25 rodenticide bait islands in the region and around the world. Based off of the their feeding habits
26 the bait availability for these gulls would be for the medium-term, the risk of mortality from
27 toxicant use would be high, and the toxicant exposure risk is high due to the range of secondary
28 toxicant exposure pathways. The duration of the risk will likely be for the medium-term due to
29 the retention time of the toxicant in the tissue of species that provide a secondary exposure
30 pathway to these gulls. The extent of the affect will be to the entire Farallones Island population.

31 ***Disturbance risk***

32 California Gulls would be exposed to disturbances from ground, air, and gull hazing operations.
33 Gull hazing will be used as a mitigation measure during aerial baiting operations to help
34 minimize the number of gulls that are likely to consume bait. The impacts associated with
35 disturbance risks for this alternative are high because gulls may be very sensitive to hazing
36 causing them to alter their feeding and roosting habits disruption their normal behavior. The
37 duration of the disturbance will be for the medium-term, and the extent of the affect will be to
38 the entire Farallones Island population.

- 39 • XXX individuals are likely to be exposed to impacts from alternative B.

40 41 **Glauous-winged Gull**

4. Environmental Consequences

Toxicant risk

California Gulls would be exposed to brodifacoum through primary and secondary exposure pathways by either directly consuming bait (primary) or consuming other species that have been exposed to the toxicant (secondary). Glaucous-winged Gulls are omnivorous and opportunistic feeders consuming fish, marine invertebrates, carrion, birds, eggs, and mice. Additionally, Gulls have been known to eat rodenticide bait islands in the region and around the world. Based off of their feeding habits the bait availability for these gulls would be for the medium-term, the risk of mortality from toxicant use would be high, and the toxicant exposure risk is high due to the range of secondary toxicant exposure pathways. The duration of the risk will likely be for the medium-term due to the retention time of the toxicant in the tissue of species that provide a secondary exposure pathway to these gulls. The extent of the affect will be to the entire Farallones Island population.

Disturbance risk

Glaucous-wing Gulls would be exposed to disturbances from ground, air, and gull hazing operations. Gull hazing will be used as a mitigation measure during aerial baiting operations to help minimize the number of gulls that are likely to consume bait. The impacts associated with disturbance risks for this alternative are high because gulls may be very sensitive to hazing causing them to alter their feeding and roosting habits disruption their normal behavior. The duration of the disturbance will be for the medium-term, and the extent of the affect will be to the entire Farallones Island population.

- XXX individuals are likely to be exposed to impacts from alternative B.

Mew Gull

Toxicant risk

Mew Gulls would be exposed to brodifacoum through primary and secondary exposure pathways by either directly consuming bait (primary) or consuming other species that have been exposed to the toxicant (secondary). Mew Gulls are omnivorous and opportunistic feeders consuming insects, worms, fish, aquatic invertebrates, mice, and carrion. Additionally, Gulls have been known to eat rodenticide bait islands in the region and around the world. Based off of their feeding habits the bait availability for these gulls would be for the medium-term, the risk of mortality from toxicant use would be high, and the toxicant exposure risk is high due to the range of secondary toxicant exposure pathways. The duration of the risk will likely be for the medium-term due to the retention time of the toxicant in the tissue of species that provide a secondary exposure pathway to these gulls. The extent of the affect will be to the entire Farallones Island population.

Disturbance risk

Mew Gulls would be exposed to disturbances from ground, air, and gull hazing operations. Gull hazing will be used as a mitigation measure during aerial baiting operations to help minimize the number of gulls that are likely to consume bait. The impacts associated with disturbance risks for this alternative are high because gulls may be very sensitive to hazing causing them to alter their feeding and roosting habits disruption their normal behavior. The duration of the disturbance will be for the medium-term, and the extent of the affect will be to the entire Farallones Island population.

4. Environmental Consequences

- XXX individuals are likely to be exposed to impacts from alternative B.

Herring Gull

Toxicant risk

Herring Gulls would be exposed to brodifacoum through primary and secondary exposure pathways by either directly consuming bait (primary) or consuming other species that have been exposed to the toxicant (secondary). Herring Gulls are omnivorous and opportunistic feeders consuming fish, invertebrates, birds, eggs, and carrion. Additionally, Gulls have been known to eat rodenticide bait islands in the region and around the world. Based off of the their feeding habits the bait availability for these gulls would be for the medium-term, the risk of mortality from toxicant use would be high, and the toxicant exposure risk is high due to the range of secondary toxicant exposure pathways. The duration of the risk will likely be for the medium-term due to the retention time of the toxicant in the tissue of species that provide a secondary exposure pathway to these gulls. The extent of the affect will be to the entire Farallones Island population.

Disturbance risk

Herring Gulls would be exposed to disturbances from ground, air, and gull hazing operations. Gull hazing will be used as a mitigation measure during aerial baiting operations to help minimize the number of gulls that are likely to consume bait. The impacts associated with disturbance risks for this alternative are high because gulls may be very sensitive to hazing causing them to alter their feeding and roosting habits disruption their normal behavior. The duration of the disturbance will be for the medium-term, and the extent of the affect will be to the entire Farallones Island population.

- XXX individuals are likely to be exposed to impacts from alternative B.

Hermann's Gull

Toxicant risk

Hermann's Gulls would be exposed to brodifacoum through primary and secondary exposure pathways by either directly consuming bait (primary) or consuming other species that have been exposed to the toxicant (secondary). Hermann's Gulls are omnivorous and opportunistic feeders consuming fish, invertebrates, birds, eggs, and carrion. Additionally, Gulls have been known to eat rodenticide bait islands in the region and around the world. Based off of the their feeding habits the bait availability for these gulls would be for the medium-term, the risk of mortality from toxicant use would be high, and the toxicant exposure risk is high due to the range of secondary toxicant exposure pathways. The duration of the risk will likely be for the medium-term due to the retention time of the toxicant in the tissue of species that provide a secondary exposure pathway to these gulls. The extent of the affect will be to the entire Farallones Island population.

Disturbance risk

Hermann's Gulls would be exposed to disturbances from ground, air, and gull hazing operations. Gull hazing will be used as a mitigation measure during aerial baiting operations to help minimize the number of gulls that are likely to consume bait. The impacts associated with disturbance risks for this alternative are high because gulls may be very sensitive to hazing

4. Environmental Consequences

1 causing them to alter their feeding and roosting habits disruption their normal behavior. The
2 duration of the disturbance will be for the medium-term, and the extent of the affect will be to
3 the entire Farallones Island population.

- 4 • XXX individuals are likely to be exposed to impacts from alternative B.

5 **Thayer's Gull**

6 ***Toxicant risk***

7 Thayer's Gulls would be exposed to brodifacoum through primary and secondary exposure
8 pathways by either directly consuming bait (primary) or consuming other species that have been
9 exposed to the toxicant (secondary). Thayer's Gulls are omnivorous and opportunistic feeders
10 consuming fish, invertebrates, berries, eggs, birds, ~~and~~ plants. Additionally, Gulls have been
11 known to eat rodenticide bait islands in the region and around the world. Based off of the their
12 feeding habits the bait availability for these gulls would be for the medium-term, the risk of
13 mortality from toxicant use would be high, and the toxicant exposure risk is high due to the range
14 of secondary toxicant exposure pathways. The duration of the risk will likely be for the medium-
15 term due to the retention time of the toxicant in the tissue of species that provide a secondary
16 exposure pathway to these gulls. The extent of the affect will be to the entire Farallones Island
17 population.

18 ***Disturbance risk***

19 Thayer's Gulls would be exposed to disturbances from ground, air, and gull hazing operations.
20 Gull hazing will be used as a mitigation measure during aerial baiting operations to help
21 minimize the number of gulls that are likely to consume bait. The impacts associated with
22 disturbance risks for this alternative are high because gulls may be very sensitive to hazing
23 causing them to alter their feeding and roosting habits disruption their normal behavior. The
24 duration of the disturbance will be for the medium-term, and the extent of the affect will be to
25 the entire Farallones Island population.

- 26 • XXX individuals are likely to be exposed to impacts from alternative B.

27 **Brown Pelican**

28 ***Toxicant risk***

29 Brown Pelicans would be exposed to brodifacoum through secondary exposure pathway by
30 consuming fish that have been exposed to the toxicant. Based off of the their feeding habits the
31 bait availability for these seabirds would be for the short-term since pelicans only consume fish
32 and bait pellets dissolve within a few hours after entering the water, the risk of mortality from
33 toxicant use would be high, and the toxicant exposure risk is low since there is only one exposure
34 pathway. The duration of the risk will likely be for the medium-term due to the retention time of
35 the toxicant in the tissue of species that provide a secondary exposure pathway to pelicans. The
36 extent of the affect will be to the few individuals that are seen at this time on the island.

37 ***Disturbance risk***

38 Brown Pelicans would be exposed to disturbances from both ground and air operations, which
39 will likely cause them to flush the area to an alternate site on the island. The impacts associated
40 with disturbance risks for this alternative are medium, the duration of the disturbance will be for

4. Environmental Consequences

1 the short-term, and the extent of the affect will be to the few individuals that are seen at this time
2 on the island.

- 3 • XXX individuals are likely to be exposed to impacts from alternative B.

4 **Cackling Goose**

5 **Toxicant risk**

6 Cackling Goose would be exposed to brodifacoum through primary and secondary exposure
7 pathways by either directly consuming bait (primary) or consuming other species that have been
8 exposed to the toxicant (secondary). Cackling Goose consume grass, grain, invertebrates, and
9 insects. Based off of the their feeding habits the bait availability for these geese would be for the
10 medium-term, the risk of mortality from toxicant use would be high, and the toxicant exposure
11 risk is high due to the range of secondary toxicant exposure pathways. The duration of the risk
12 will likely be for the medium-term due to the retention time of the toxicant in the tissue of
13 species that provide a secondary exposure pathway to these geese. The extent of the affect will
14 be to the few individuals that are seen at this time on the island.

15 **Disturbance risk**

16 Cackling Goose would be exposed to disturbances from both ground and air operations, which
17 will likely cause them to flush the area to an alternate site on the island. The impacts associated
18 with disturbance risks for this alternative are medium, the duration of the disturbance will be for
19 the short-term, and the extent of the affect will be to the few individuals that are seen at this time
20 on the island.

- 21 • XXX individuals are likely to be exposed to impacts from alternative B.

22 4.4.4.4.2 Impacts on Mammals

23 Non-breeding Pinnipeds:

24 Stellar's Sea Lion, California Sea Lion, Northern Fur Seal, and Pacific Harbor Seal

25 **Toxicant risk**

26 Stellar's Sea Lions, California Sea Lions, Northern Fur Seals, and Pacific Harbor Seals are at no
27 risk of toxicant exposure because they rarely if ever feed on anything other than marine fish. We
28 would mitigate impacts to fish by hand baiting near the shoreline and utilizing a deflector to
29 prevent bait from entering the waterways; therefore, the extent of the affect is insignificant and
30 does not require further scrutiny.

31 **Disturbance risk**

32 Pinnipeds would be exposed to disturbances from both ground and air operations, which will
33 likely cause them to flee the area potentially injuring themselves or others. The impacts
34 associated with disturbance risks for this alternative are high, the duration of the disturbance will
35 be for the short-term, and the extent of the affect will be to the island population.

36 Breeding Pinnipeds:

37 Northern Elephant Seal

4. Environmental Consequences

1 **Toxicant risk**

2 Northern Elephant Seals are at no risk of toxicant exposure because they rarely if ever feed on
3 anything other than marine fish. We would mitigate impacts to fish by hand baiting near the
4 shoreline and utilizing a deflector to prevent bait from entering the waterways; therefore, the
5 extent of the affect is insignificant and does not require further scrutiny.

6 **Disturbance risk**

7 Northern Elephant Seals would be exposed to disturbances from both ground and air operations,
8 which will likely cause them to flee the area potentially injuring themselves or others. The
9 impacts associated with disturbance risks for this alternative are high, the duration of the
10 disturbance will be for the short-term, and the extent of the affect will be to the island
11 population.

12
13 4.4.4.4.3 Bats:

14
15 **Insectivorous Bats**

16 **Toxicant risk**

17 Bats would be exposed to brodifacoum through secondary exposure pathways by consuming
18 insects that have been exposed to the toxicant. Based off of the their feeding habits the bait
19 availability for these bats would be for the medium-term, the risk of mortality from toxicant use
20 would be high, and the toxicant exposure risk is **medium** due to the range of secondary toxicant
21 exposure pathways. The duration of the risk will likely be for the medium-term due to the
22 retention time of the toxicant in the tissue of species that provide a secondary exposure pathway
23 to bats. The extent of the affect will be to the few individuals that are seen at this time on the
24 island.

25 **Disturbance risk**

26 Bats **will not be disturbed** by eradication operations on the South Farallon Island; therefore no
27 further analysis is required.

28
29 4.4.4.4.4 Impacts to Herbivores

30
31 **Salamanders:**

32
33 **Arboreal Salamanders**

34 **Toxicant risk**

35 Arboreal Salamanders would be exposed to brodifacoum through secondary exposure pathways
36 by consuming insects that have been exposed to the toxicant. Based off of the their feeding
37 habits the bait availability for these **shorebirds** would be for the medium-term, the risk of
38 mortality from toxicant use would be **high**, and the toxicant exposure risk is medium due to the
39 range of secondary toxicant exposure pathways. The duration of the risk will likely be for the
40 medium-term due to the retention time of the toxicant in the tissue of species that provide a
41 secondary exposure pathway to salamanders. The extent of the affect will be to the global
42 population of this subspecies of Arboreal Salamanders since they are endemic to the South
43 Farallon Islands.

4. Environmental Consequences

Disturbance risk

Arboreal Salamanders would be exposed to disturbances from both ground and air operations, which will likely cause them to flee the area potentially injuring themselves or others. Additionally, they may be crushed by personnel moving around the island since they burrow underground. The impacts associated with disturbance risks for this alternative are high, the duration of the disturbance will be for the short-term, and the extent of the affect will be to the global population of this subspecies of Arboreal Salamanders since they are endemic to the South Farallon Islands.

4.4.4.4.5 Impacts to Fish

Marine Fish:

Marine Fish

Toxicant risk

Marine Fish would be exposed to brodifacoum through secondary exposure pathways by consuming insects that have been exposed to the toxicant. Based off of the their feeding habits the bait availability for these fish would be for the short-term since bait pellets will dissolve within a few hours, the risk of mortality from toxicant use would be high, and the toxicant exposure risk is medium due to the range of secondary toxicant exposure pathways. The duration of the risk will likely be for the medium-term due to the retention time of the toxicant in the tissue of species that provide a secondary exposure pathway to salamanders. The extent of the affect will be to the a few individuals.

Disturbance risk

Marine Fish would be exposed to disturbances from boating operations, which will likely cause them to flee. The impacts associated with disturbance risks for this alternative are low, the duration of the disturbance will be for the short-term, and the extent of the affect will be to individuals.

4.4.4.4.6 Impacts to Invertebrates

Invertebrates:

Intertidal Invertebrates

Toxicant risk

Intertidal Invertebrates are not known to be negatively impacted by rodenticides, and therefore, do not require further analysis of the toxicological impacts.

Disturbance risk

Intertidal Invertebrates would be exposed to disturbances from ground operations, which will likely crush individuals. The impacts associated with disturbance risks for this alternative are low, the duration of the disturbance will be for the short-term, and the extent of the affect will be to a few individuals.

4. Environmental Consequences

1 **Cave Crickets**

2 ***Toxicant risk***

3 Cave Crickets are not known to be negatively impacted by rodenticides, and therefore, do not
4 require further analysis of the toxicological impacts.

5 ***Disturbance risk***

6 Cave Crickets would be exposed to disturbances from ground operations, which will likely cause
7 them to flee the area and may impact their feeding habits. The impacts associated with
8 disturbance risks for this alternative are medium, the duration of the disturbance will be for the
9 short-term, and the extent of the affect will be to the global population since these crickets are
10 endemic to the South Farallon Islands.

11
12 4.4.4.4.7 Impacts to Vegetation

13
14 **Vegetation**

15 ***Toxicant risk***

16 Vegetation is not known to be negatively impacted by rodenticides, and therefore, does not
17 require further analysis of the toxicological impacts.

18 ***Disturbance risk***

19 Vegetation would be exposed to disturbances from ground operations, which will likely crush
20 individuals and possibly damage plants. The impacts associated with disturbance risks for this
21 alternative are medium, the duration of the disturbance will be for the short-term, and the extent
22 of the affect will be to a few plants.

23
24 4.4.4.4.8 Impacts Table for Alternative B on Biological Resources: Aerial Broadcast of
25 Brodifacoum

Table X. Impacts of Alternative B on Biological Resources

Species	Bait avail-ability ¹	Risk mortality - toxicant use ²	Toxicant exposure risk level ³	Disturbance risk ⁴	Extent of risk within a population ⁵		Duration of risk ⁶	
					toxicant	disturbance	toxicant	disturbance
Raptors (general) ⁷	Medium	High	High	Low	Individ.	Individ.	Medium	Short
White-tailed Kite	Medium	High	Medium	Low	Individ.	Individ.	Medium	Short

4.4.4.5 Impacts of Alternative C on Biological Resources: Bait Station with Brodifacoum

Comment [g106]: Add analysis in next draft

4.4.4.6 Impacts of Alternative D on Biological Resources: Phased Aerial Brodifacoum

Comment [g107]: Add analysis in next draft

4.5 Consequences: Social and Economic Environment

4. Environmental Consequences

1 The CEQ guidelines at 40 CFR 1508.14 include the human relationship with the natural
2 environment as a category of potential impacts that must be considered in a NEPA analysis. This
3 is interpreted to mean that a NEPA analysis needs to examine the potential effects of an action
4 on any economic and/or social values that are related to the natural environment.
5

6 **4.5.1 Refuge Visitors and Recreation**

7 *4.5.1.1 Analysis framework for Refuge visitors and recreation*

8
9
10 Although public access to the South Farallones is prohibited, the waters surrounding the islands
11 are popular with tour boats and private boaters for wildlife viewing, as well as recreational
12 fishing. Furthermore, the islands themselves are a high-quality scenic panorama, which draws
13 tourists throughout the year. This analysis will examine the likely changes to visitor experience
14 as a result of both of the action alternatives. The Service would consider any major, long-term
15 changes to the visitor experience to be significant.
16

17 *4.5.1.2 Alternative A: No action*

18
19 It is unlikely that the impacts that mice would continue to have to the South Farallones
20 ecosystem would be perceptible to boaters near the islands. While the ash and Leach's storm-
21 petrel populations would likely continue to be negatively impacted, these birds are nocturnal at
22 the colony and forage far offshore and thus are rarely seen near the island. Overall, taking no
23 action with regard to non-native mice would be unlikely to have any direct or indirect impacts to
24 the value of the South Farallones to Refuge visitors.
25

26 *4.5.1.3 Alternative B: Aerial Brodifacoum*

27
28 The **area immediately** surrounding the South Farallones would be closed to access by boaters
29 during aerial bait application operations, which would be a minor short-term inconvenience to
30 Refuge visitors. ~~If flocks of roosting seabirds, particularly gulls or pelicans, are flushed during~~
~~31 helicopter operations the flocks would be visible to boaters offshore; but only during the short~~
~~32 period that helicopters would be operational.~~ The expected recovery of the South Farallones
33 ecosystem after mouse eradication would likely not be perceptible to boaters near the islands.
34 However, interpretive materials on the islands' ecosystem recovery would be available in San
35 Francisco Bay National Wildlife Refuge Complex visitor's center and other appropriate venues.
36

37 **4.5.1.4 Alternative C: Bait Station with Brodifacoum**

38
39 The area immediately surrounding the South Farallones would be closed to access by boaters
40 during aerial bait application operations, which would be a minor short-term inconvenience to
41 Refuge visitors. Additionally, the bait station grid would alter the appearance of the islands for
42 up to two years. If flocks of seabirds, particularly gulls, pelicans, or common murrelets, are flushed
43 during bait station maintenance or helicopter operations, the flocks would be visible to boaters
44 offshore. The negative impacts to seabird populations on the islands as a result of disturbance in
45 Alternative C would likely not be perceptible to boaters near the islands. The subsequent
46 expected recovery of aspects of the South Farallones ecosystem after mouse eradication would
47 similarly likely not be perceptible to boaters near the islands. However, interpretive materials on

4. Environmental Consequences

1 the islands' ecosystem recovery would be available in San Francisco Bay National Wildlife
2 Refuge Complex visitor's center and other appropriate venues.

4.5.1.5 Alternative D: Phased Aerial Brodifacoum

6 The area immediately surrounding the South Farallones would be closed to access by boaters
7 during aerial bait application operations, which would be a minor short-term inconvenience to
8 Refuge visitors. If flocks of roosting seabirds, particularly gulls or pelicans, are flushed during
9 helicopter operations the flocks would be visible to boaters offshore, but only during the short
10 period that helicopters would be operational. The expected recovery of the South Farallones
11 ecosystem after mouse eradication would likely not be perceptible to boaters near the islands.
12 However, interpretive materials on the islands' ecosystem recovery would be available in San
13 Francisco Bay National Wildlife Refuge Complex visitor's center and other appropriate venues.

4.5.2 Fishing Resources

4.5.2.1 Analysis framework for fishing resources

20 The Service would consider any noticeable, long-term changes to fishing resources surrounding
21 the South Farallones that could be attributable to the mouse eradication significant.

4.5.2.2 Alternative A: No action

25 Mice on the South Farallones do not currently affect the fisheries of the nearshore waters, nor
26 would the Service expect any future impacts.

4.5.2.3 Alternative B: Aerial Brodifacoum

30 The area immediately surrounding the South Farallones would be closed to access by boats
31 during aerial bait application operations, which would be a minor short-term inconvenience to
32 fishing vessels. There would be no further impacts to fishing resources. If the State of California
33 completes the establishment of Southeast Farallon Island Marine Reserve, barring fishing from
34 the waters immediately surrounding the Farallones, before the proposed action is implemented,
35 the impact of this action to fisheries would be moot.

Comment [g108]: Is this true now?

4.5.2.4 Alternative C: Bait Station with Brodifacoum

38 The area immediately surrounding the South Farallones would be closed to access by boats
39 during aerial bait application operations, which would be a minor short-term inconvenience to
40 fishing vessels. There would be no further impacts to fishing resources. If the State of California
41 completes the establishment of Southeast Farallon Island Marine Reserve, barring fishing from
42 the waters immediately surrounding the Farallones, before the proposed action is implemented,
43 the impact of this action to fisheries would be moot.

Comment [g109]: Is this true now?

4.5.2.5 Alternative D: Phased Aerial Brodifacoum

4. Environmental Consequences

1 The area immediately surrounding the South Farallones would be closed to access by boats
2 during aerial bait application operations, which would be a minor short-term inconvenience to
3 fishing vessels. There would be no further impacts to fishing resources. If the State of California
4 completes the establishment of Southeast Farallon Island Marine Reserve, barring fishing from
5 the waters immediately surrounding the Farallones, before the proposed action is implemented,
6 the impact of this action to fisheries would be moot.

Comment [g110]: Is this true now?

4.5.3 Historical and Cultural Resources

4.5.3.1 Analysis framework for historical and cultural resources

12 The National Historic Preservation Act (NHPA) defines the concept of an “adverse impact” to
13 historical resources, but the regulations make clear that “a finding of adverse effect on a historic
14 property does not necessarily require an EIS under NEPA” (36 CFR 800.8(a)(1)). Section 106 of
15 the NHPA requires agencies to consult with the appointed regional Historic Preservation
16 Officer(s) if adverse impacts to historical or cultural resources are possible. This analysis will
17 describe the potential impacts to historical and cultural resources on the South Farallones as a
18 reference for consultation with the appropriate Historic Preservation Officers.

Comment [g111]: Have we consulted with the archaeologist?

4.5.3.2 Alternative A: No action

22 The Service has no evidence that mouse activities affect historical and cultural resources on the
23 island. Mice are burrowing animals, a behavior that has the potential to damage buried artifacts,
24 but there are numerous seabird species that burrow on the island as well, which makes the
25 preservation of buried artifacts on the South Farallones difficult, whether or not mice are present.
26 Mice may continue to cause damage to the historical buildings on Southeast Farallon, but this
27 damage would likely be minor and would not likely be irreversible.

4.5.3.3 Alternative B: Aerial Brodifacoum

31 Alternative B would not involve activities that would require soil disruption or any other actions
32 that would affect the historical or cultural resources on the South Farallones.

4.5.3.4 Alternative C: Bait Station with Brodifacoum

36 The bait station grid required under Alternative C could have minor impacts on historical or
37 cultural resources that are buried on the islands. To minimize impacts, the final grid placement
38 would be determined in consultation with experts in the Farallones’ historical and cultural
39 resources including the State Historical Preservation Officer.

Comment [g112]: Have we started to develop this final bait station grid? We should include a bit more detail on the impact for the final draft.

4.5.3.5 Alternative D: Phased Aerial Brodifacoum

43 Alternative D would not involve activities that would require soil disruption or any other actions
44 that would affect the historical or cultural resources on the South Farallones.

4.6 Consequences: Cumulative Impacts

4. Environmental Consequences

4.6.1 Assessing Cumulative Impacts

The NEPA regulations require Federal agencies to consider not just the direct and indirect impacts of an action but also the cumulative impacts to which an action would contribute. Analyzing cumulative impacts on the South Farallones requires consideration of other, unrelated impacts that are occurring simultaneously to those resources, impacts that have occurred in the past, or impacts that are likely to occur in the foreseeable future. The continued presence of mice is likely impacting many of the species on the island, but there are no other clear localized impacts known to occur at this time. Furthermore, there are no foreseeable future human actions on the island that are likely to negatively impact the island's environment, because the land is being managed in perpetuity as a National Wildlife Refuge. However, many of the species of the Farallones are still recovering from severe past impacts, including the impacts of introduced rabbits on the South Farallones, hunters and egg collectors that visited the islands, and past oil spills and other pollution. Also, many of the species that utilize the South Farallones have large ranges. These far-ranging populations may have been impacted in the past, may be currently experiencing unrelated impacts, or may be at risk of impacts from reasonably foreseeable consequences in the future, elsewhere in their ranges.

Comment [g113]: This section needs to include past, present, and future project analysis for cumulative impacts. Refer to Palmyra!

4.6.2 Cumulative Impacts Under Alternative A (No Action)

The impacts that mice are having to the environment of the South Farallones, particularly on the islands' biological resources, would continue in perpetuity under the no action alternative. These impacts could be additive to other unrelated impacts on these resources in the future. For example, the ongoing indirect impact that mice currently have to storm-petrels at the colony, in combination with possible major future changes in the productivity of the marine waters of the California Current ecosystem on which these storm-petrels depend, could ultimately result in the disappearance of the South Farallones ashy and Leach's storm-petrel colonies. However, the likelihood of this kind of future cumulative impact to the South Farallones' biological resources is difficult to predict with certainty.

The continued presence of mice would not be likely to contribute to cumulative impacts to any other (non-biological) resources on the South Farallones.

4.6.3 Cumulative Impacts Under Alternative B

There would be no major negative impacts to the environment of the South Farallones under Alternative B. The minor negative impacts to biological resources on the islands as a result of Alternative B would not be likely to contribute additively to any ongoing unrelated impacts. Similarly, the expected positive impacts of Alternative B to the islands' biological resources would not be likely to contribute additively to cumulative impacts.

Alternative B would be limited in scope to the South Farallones, and in duration to the short period of time required for aerial bait application. It would be the first successful island mouse eradication in the United States, which could set a precedent for future actions, but the effects of these future actions would be, at this point, purely speculative.

42
43
44
45
46

4.6.4 Cumulative Impacts Under Alternative C

Alternative C could result in major negative impacts to breeding seabirds on the South Farallones. These impacts could be additive to other unrelated impacts on seabirds in the future. However, the likelihood of future impacts to these seabirds is difficult to predict. On the South Farallones, the islands' status as a National Wildlife Refuge would protect seabirds from further harm within the Refuge, assuming that the current restrictions on island access continued. Since seabirds have large ranges, further negative impacts to these birds elsewhere in their ranges are possible but the intensity of these impacts would be difficult to predict.

Alternative C would be limited in scope to the South Farallones, and in duration to the time required for the bait station approach to ensure eradication success. It would be the first successful island mouse eradication in the United States, which could set a precedent for future actions, but the impacts of these future actions would be, at this point, purely speculative.

4.6.5 Cumulative Impacts Under Alternative D

There would be no major negative impacts to the environment of the South Farallones under Alternative D. The minor negative impacts to biological resources on the islands as a result of Alternative D would not be likely to contribute additively to any ongoing unrelated impacts. Similarly, the expected positive impacts of Alternative D to the islands' biological resources would not be likely to contribute additively to cumulative impacts.

Alternative D would be limited in scope to the South Farallones, and in duration to the short period of time required for aerial bait application. It would be the first successful island mouse eradication in the United States, which could set a precedent for future actions, but the effects of these future actions would be, at this point, purely speculative.

4.7 Irreversible and Irretrievable Impacts

4.7.1 Alternative A (No Action)

Pressure from non-native house mice could contribute to declines in the native biological resources of the South Farallones to below the level of population viability. For ashy and Leach's storm-petrels, in particular, their recent population declines indicate a risk for an irreversible decline in the future. However, at this time there is no strong evidence to support this assertion.

4.7.2 Alternative B

Mouse eradication would likely eliminate the overwintering burrowing owl population on the South Farallones, although this would be to the benefit of the individual owls that arrive on the islands because they would continue their migrations rather than attempting to overwinter in the poor habitat of the South Farallones. Mouse eradication would also likely result in positive population-level changes for ashy and Leach's storm-petrels.

4. Environmental Consequences

1
2 Project activities under Alternative B would require a commitment of funds that would then be
3 unavailable for use on other Service projects. At some point, commitment of funds (for purchase
4 of supplies, payments to contractors, etc.) would be irreversible; once used, these funds would be
5 irretrievable. Nonrenewable or nonrecyclable resources committed to the project (such as
6 helicopter fuel, bait, and bait stations) would also represent an irreversible or irretrievable
7 commitment of resources.

8 9 **4.7.3 Alternative C**

10
11 Mouse eradication would be likely to eliminate the overwintering burrowing owl population on
12 the South Farallones, although this would be to the benefit of the individual owls that arrive on
13 the islands because they would continue their migrations rather than attempting to overwinter in
14 the poor habitat of the South Farallones. Mouse eradication would also be likely to result in
15 positive population-level changes for ash and Leach's storm-petrels.

16
17 On the other hand, Alternative C would lead to significant impacts to seabird populations on the
18 South Farallones. Seabirds often recover very slowly from negative impacts to their populations.
19 However, the impacts under Alternative C would not be irreversible. After the bait station grid is
20 removed, seabird populations that were significantly affected would be likely to recover in the
21 long term.

22
23 Similar to Alternative B, project activities would require a commitment of funds (for purchase of
24 supplies, payments to contractors, etc.) that would be irreversible; once used, these funds would
25 be irretrievable. Nonrenewable or nonrecyclable resources committed to the project (such as
26 helicopter fuel, bait, and bait stations) would also represent an irreversible or irretrievable
27 commitment of resources.

28 29 **4.7.4 Alternative D**

30
31 Mouse eradication would likely eliminate the overwintering burrowing owl population on the
32 South Farallones, although this would be to the benefit of the individual owls that arrive on the
33 islands because they would continue their migrations rather than attempting to overwinter in the
34 poor habitat of the South Farallones. Mouse eradication would also likely result in positive
35 population-level changes for ash and Leach's storm-petrels.

36
37 Project activities from Alternative D would require a commitment of funds that would then be
38 unavailable for use on other Service projects. At some point, commitment of funds (for purchase
39 of supplies, payments to contractors, etc.) would be irreversible; once used, these funds would be
40 irretrievable. Nonrenewable or nonrecyclable resources committed to the project (such as
41 helicopter fuel, bait, and bait stations) would also represent an irreversible or irretrievable
42 commitment of resources.

43 44 **4.8 Short-term Uses and Long-term Productivity**

4. Environmental Consequences

1 An important goal of the Service is to maintain the long-term ecological productivity and
2 integrity of the biological resources on the Refuge. The action alternatives are designed to
3 contribute to the long-term ecological productivity of the South Farallones, and would not result
4 in short-term uses of the resources that would counteract ~~this long-term productivity~~. Any short-
5 term negative impacts to the islands' biological resources would be outweighed by the
6 ecosystem's long-term restoration through the eradication of mice.

26 amended)
27 Curation of Federally Owned and Administered Archeological Collections (36 CFR 79)
28 Executive Memorandum – Government-to-Government Relations with Native American Tribal
29 Governments (59 FR 85, April 29, 1994)
30 Executive Order 13007 – Indian Sacred Sites (61 FR 104, May 24, 1996)
31 Executive Order 13175 – Consultation and Coordination with Indian Tribal Governments (65 FR
32 218, November 9, 2000)

33
34
35 **5.2.2. California State Laws and Authorities**

36 California Coastal Commission
37 Regional Water Quality Control Board
38 Pesticide regulations?
39
40
41 *California Department of Fish and Game* – The California Department of Fish and Game
42 (CDFG) has jurisdiction over the conservation, protection, and management of fish, wildlife,
43 native plants, and the habitats necessary for biologically sustainable populations of those species
44 (California Fish and Game Code Section 1802). California’s fish and wildlife resources,
45 including their habitats, are held in trust for the people of the California by the CDFG (California
46 Fish and Game Code Section 711.7). The CDFG’s fish and wildlife management functions are

5. Consultation and Coordination

1 implemented through its administration and enforcement of the Fish and Game Code (Fish and
2 Game Code Section 702). The CDFG is entrusted to protect state-listed threatened and
3 endangered species under the California Endangered Species Act (Fish and Game Code Sections
4 2050-2115.5) (CESA).

5
6 The CDFG generally does not have jurisdiction to manage or regulate natural resources on
7 federal lands, such as the Farallon Islands, where the federal government has exclusive
8 jurisdiction. It also does not regulate federal government agency activities. Although the CDFG
9 does not regulate fish and wildlife resources on the Farallones, the Service regularly coordinates
10 with the CDFG to ensure the proper protection of the island's natural resources. Thus, while
11 CESA restrictions do not apply to the proposed restoration project on the South Farallones, the
12 Service would continue to coordinate with CDFG regarding actions that could potentially affect
13 state-listed species and the proposed conservation measures designed to avoid or minimize
14 adverse effects.

17 5.3. Inter-Agency Scoping and Review

18
19 U.S. Coast Guard
20 Gulf of the Farallones National Marine Sanctuary (NOAA – Sanctuaries)
21 Golden Gate National Recreation Area (NPS)
22 Natural Resource Agency Trustees for the S.S. Luckenbach and associated oil spills
23 California Department of Fish & Game
24 National Oceanic and Atmospheric Administration
25 U.S. Fish & Wildlife Service
26 National Park Service
27 U.S. EPA
28 National Wildlife Research Center (USDA-APHIS)
29 CA EPA
30 National Marine Fisheries Service (NOAA)
31 U.S. Fish & Wildlife Service – Ecological Services
32
33

34 5.4. Public Scoping and Review

35
36 As part of the project scoping process, the Service opened a 45-day public comment period from
37 April 14, 2006 through May 29, 2006 during which interested members of the public were
38 encouraged to comment on the scope of the project and the important environmental issues to be
39 addressed in NEPA analysis. The Service received substantive comments from 15 individuals or
40 organizations during this comment period, as well as at least three requests to be added to a
41 distribution list for future information on the proposed project. The Service took all substantive
42 comments into consideration during the preparation of this EA.

43
44 This Draft Environmental Assessment will be made available for review by the public, and the
45 Service will again open a 45-day comment period to allow the public to provide input on the
46 content of the EA. This comment period will include at least one public information session,

5. Consultation and Coordination

1 during which Service staff and partners will be available to provide information and answer
2 questions in person. Availability of the Draft EA and information on the comment period and
3 public information sessions will be advertised in the Federal Register, by mail to all interested
4 parties who have requested information, and in local media as appropriate. After the comment
5 period closes, the Service will address all substantive comments received, make changes to the
6 EA if necessary, and circulate the Final EA along with all substantive public comments and/or a
7 summary of public comments if a large number are received.

Appendix B. Designated Wilderness, South Farallon Islands.

Appendix C. Regular breeding birds on the South Farallones

Deleted: Breeding

Common name	Scientific name
Leach's storm-petrel	<i>Oceanodroma leucorhoa</i>
Ashy storm-petrel	<i>Oceanodroma homochroa</i>
Brandt's cormorant	<i>Phalacrocorax penicillatus</i>
Double-crested cormorant	<i>Phalacrocorax auritus</i>
Pelagic cormorant	<i>Phalacrocorax pelagicus</i>
Black oystercatcher	<i>Haematopus bachmani</i>
California gull	<i>Larus californicus</i>
Western gull	<i>Larus occidentalis</i>
Common murre	<i>Uria aalge</i>
Pigeon guillemot	<i>Cephus columba</i>
Cassin's auklet	<i>Ptychoramphus aleuticus</i>
Rhinoceros auklet	<i>Cerorhinca monocerata</i>
Tufted puffin	<i>Fratercula cirrhata</i>

ADMINISTRATIVE REVIEW DRAFT

Appendix D. Risk profiles of birds on the South Farallones

Methods

1
2 We synthesized published bird records from DeSante and
3 Ainley 1980, Ainley and Boekelheide 1990, Richardson et al.
4 2003, and unpublished bird records from PRBO and USFWS,
5 into a single database. The published sources each present bird
6 records grouped roughly into three “seasons” with similar
7 dates. Richardson et al. use the following seasonal definitions,
8 which we used except where noted:
9 1. Fall = July 15 – December 19
10 2. Winter = December 20 – February 28 (or 29)
11 3. Spring = March 1 – July 14
12
13 The published sources also specifically identified birds that
14 were present for more than three weeks at a time during the
15 winter, categorized as “winter residents.”
16
17 We calculated the average occurrence rate of each bird species
18 per season, and assigned abundance “scores” adapted from
19 DeSante and Ainley (1980):
20 • Abundant = 90 birds per season or greater
21 • Common = 30-89 birds per season
22 • Fairly common = 10-29 birds per season
23 • Uncommon = 3-9 birds per season
24 • Rare = 1-2 birds per season
25 • Very rare = 1/3 - 1 bird per season
26 • Extremely rare = less than 1/3 bird per season
27
28

29 In most cases, we then removed birds that were extremely rare
30 or very rare in all seasons. To identify bird species present
31 under Alternative B, which would occur within a discrete time
32 period, we removed birds that were extremely rare or very rare
33 specifically in winter. However, in some cases, we included
34 birds that were classified as extremely rare or very rare based
35 on published bird records, but were identified by PRBO and/or
36 USFWS biologists as likely to be present.
37

Birds present under Alternative B

Herbivores (Alternative B risk profile: *initially high-risk*)

Bird	Scientific name	Abundance index		References
		Winter	Winter residents	
Canada goose	<i>Branta Canadensis</i>	Very rare	Extremely rare	Richardson et al. 2003; FWS pers. comm.
Fox sparrow	<i>Passerella iliaca</i>	Very rare	Rare	Richardson et al. 2003; PRBO unpubl. data
White-crowned sparrow	<i>Zonotrichia leucophrys</i>	Very rare	Very rare	Richardson et al. 2003; PRBO unpubl. data
Golden-crowned sparrow	<i>Zonotrichia atricapilla</i>	Very rare	Uncommon	Richardson et al. 2003; PRBO unpubl. data
Dark-eyed junco	<i>Junco hyemalis</i>	Rare	Extremely rare	Richardson et al. 2003
Pine siskin	<i>Carduelis pinus</i>	Rare	Extremely rare	Richardson et al. 2003

Predators/scavengers* (Alternative B risk profile: *initially high-risk*)

Bird	Scientific name	Abundance index		References
		Winter	Winter residents	
Northern harrier	<i>Circus cyaneus</i>	Possible	Absent	Richardson et al. 2003; PRBO unpubl. data
Red-tailed hawk	<i>Buteo jamaicensis</i>	Possible	Extremely rare	Richardson et al. 2003; PRBO unpubl. data
Black-bellied plover	<i>Pluvialis squatarola</i>	Very rare	Fairly common	Richardson et al. 2003; PRBO unpubl. data
Killdeer	<i>Charadrius vociferus</i>	Uncommon	Very rare	Richardson et al. 2003
Black oystercatcher	<i>Haematopus bachmani</i>	Common	Common	DeSante & Ainley 1980; Ainley & Boekelheide 1990
Heermann's gull	<i>Larus heermanni</i>	Uncommon	Rare	Richardson et al. 2003
Mew gull	<i>Larus canus</i>	Uncommon	Very rare	Richardson et al. 2003

D. Risk profiles for birds

Predators/scavengers* (Alternative B risk profile: *initially high-risk*)

Bird	Scientific name	Abundance index		References
		Winter	Winter residents	
California gull	<i>Larus californicus</i>	Common	Extremely rare	Richardson et al. 2003; PRBO unpubl. data
Herring gull	<i>Larus argentatus</i>	Abundant	Fairly common	Richardson et al. 2003; PRBO unpubl. data
Thayer's gull	<i>Larus thayeri</i>	Uncommon	Extremely rare	Richardson et al. 2003
Western gull	<i>Larus occidentalis</i>	Abundant	Abundant	DeSante & Ainley 1980; Ainley & Boekelheide 1990
Glaucous-winged gull	<i>Larus glaucescens</i>	Abundant	Common	Richardson et al. 2003; PRBO unpubl. data
Barn owl	<i>Tyto alba</i>	Possible	Extremely rare	PRBO unpubl. data
Burrowing owl	<i>Athene cunicularia</i>	Extremely rare	Uncommon	Richardson et al. 2003; PRBO unpubl. data
Long-eared owl	<i>Asio otus</i>	Possible	Absent	Richardson et al. 2003; PRBO unpubl. data
Short-eared owl	<i>Asio flammeus</i>	Possible	Extremely rare	Richardson et al. 2003; PRBO unpubl. data
Northern saw-whet owl	<i>Aegolius acadicus</i>	Possible	Absent	PRBO unpubl. data
Hermit thrush	<i>Catharus guttatus</i>	Uncommon	Very rare	Richardson et al. 2003
American robin	<i>Turdus migratorius</i>	Fairly common	Extremely rare	Richardson et al. 2003; PRBO unpubl. data
Varied thrush	<i>Ixoreus naevius</i>	Rare	Extremely rare	Richardson et al. 2003
European starling	<i>Sturnus vulgaris</i>	Abundant	Abundant	Richardson et al. 2003
Western meadowlark	<i>Sturnella neglecta</i>	Very rare	Uncommon	Richardson et al. 2003

*Not including specialists in birds, intertidal organisms, flying insects or micro-invertebrates

D. Risk profiles for birds

Other terrestrial birds* (Alternative B risk profile: *initially low risk*)

Bird	Scientific name	Abundance index		References
		Winter	Winter residents	
Sharp-shinned hawk	<i>Accipiter striatus</i>	Possible	Absent	Richardson et al. 2003; PRBO unpubl. data
Peregrine falcon	<i>Falco peregrinus</i>	Very rare	Uncommon	Richardson et al. 2003; PRBO unpubl. data
Wandering tattler	<i>Tringa incana</i>	Very rare	Fairly common	Richardson et al. 2003; PRBO unpubl. data
Willet	<i>Tringa semipalmata</i>	Extremely rare	Fairly common	Richardson et al. 2003; PRBO unpubl. data
Whimbrel	<i>Numenius phaeopus</i>	Extremely rare	Fairly common	Richardson et al. 2003; PRBO unpubl. data
Ruddy turnstone	<i>Arenaria interpres</i>	Very rare	Uncommon	Richardson et al. 2003
Black turnstone	<i>Arenaria melanocephala</i>	Uncommon	Common	Richardson et al. 2003; PRBO unpubl. data
Black phoebe	<i>Sayornis nigricans</i>	Very rare	Uncommon	Richardson et al. 2003; PRBO unpubl. data
Yellow-rumped warbler	<i>Dendroica coronata</i>	Fairly common	Uncommon	Richardson et al. 2003; PRBO unpubl. data

*Specialists in birds, intertidal organisms, flying insects or micro-invertebrates

Marine foragers (Alternative B risk profile: *negligible risk*)

Bird	Scientific name	Abundance index		References
		Winter	Winter residents	
Surf scoter	<i>Melanitta perspicillata</i>	Fairly common	Fairly common	Richardson et al. 2003
Pacific loon	<i>Gavia pacifica</i>	Abundant	Rare	Richardson et al. 2003

D. Risk profiles for birds

Marine foragers (Alternative B risk profile: *negligible risk*)

Bird	Scientific name	Abundance index		References
		Winter	Winter residents	
Common loon	<i>Gavia immer</i>	Fairly common	Extremely rare	Richardson et al. 2003
Eared grebe	<i>Podiceps nigricollis</i>	Abundant	Abundant	Richardson et al. 2003
Western / Clark's grebe	<i>Aechmophorus occidentalis</i> / <i>A. clarkii</i>	Rare	Very rare	Richardson et al. 2003
Northern fulmar	<i>Fulmarus glacialis</i>	Abundant	Absent	Richardson et al. 2003
Sooty shearwater	<i>Puffinus griseus</i>	Fairly common	Absent	Richardson et al. 2003
Ashy storm-petrel	<i>Oceanodroma homochroa</i>	Abundant	Abundant	DeSante & Ainley 1980; Ainley & Boekelheide 1990
Brown pelican	<i>Pelecanus occidentalis</i>	Abundant	Absent	Richardson et al. 2003; PRBO unpubl. data
Brandt's cormorant	<i>Phalacrocorax penicillatus</i>	Abundant	Abundant	DeSante & Ainley 1980; Ainley & Boekelheide 1990
Pelagic cormorant	<i>Phalacrocorax pelagicus</i>	Abundant	Abundant	DeSante & Ainley 1980; Ainley & Boekelheide 1990
Red phalarope	<i>Phalaropus fulicarius</i>	Fairly common	Absent	Richardson et al. 2003
Black-legged kittiwake	<i>Rissa tridactyla</i>	Abundant	Absent	Richardson et al. 2003
Common murre	<i>Uria aalge</i>	Abundant	Abundant	DeSante & Ainley 1980; Ainley & Boekelheide 1990
Ancient murrelet	<i>Synthliboramphus hypoleucus</i>	Fairly common	Rare	Richardson et al. 2003

D. Risk profiles for birds

Marine foragers (Alternative B risk profile: *negligible risk*)

Bird	Scientific name	Abundance index		References
		Winter	Winter residents	
Cassin's auklet	<i>Ptychoramphus aleuticus</i>	Abundant	Abundant	DeSante & Ainley 1980; Ainley & Boekelheide 1990
Rhinoceros auklet	<i>Cerorhinca monocerata</i>	Uncommon	Uncommon	DeSante & Ainley 1980; Ainley & Boekelheide 1990

Birds present under Alternative C

Herbivores (Alternative C risk profile: *primarily low risk; high risk during bait broadcast*)

Bird	Scientific name	Abundance index				References
		Fall	Winter	Winter residents	Spring	
Greater white-fronted goose	<i>Anser albifrons</i>	Fairly common	Extremely rare	Absent	Extremely rare	Richardson et al. 2003
Brant	<i>Branta bernicla</i>	Abundant	Extremely rare	Extremely rare	Common	Richardson et al. 2003
Canada goose	<i>Branta canadensis</i>	Fairly common	Very rare	Extremely rare	Extremely rare	Richardson et al. 2003
Mourning dove	<i>Zenaida macroura</i>	Fairly common	Extremely rare	Absent	Uncommon	Richardson et al. 2003
Horned lark	<i>Eremophila alpestris</i>	Uncommon	Absent	Absent	Extremely rare	Richardson et al. 2003
American (Water) pipit	<i>Anthus rubescens</i>	Abundant	Extremely rare	Absent	Very rare	Richardson et al. 2003

D. Risk profiles for birds

Herbivores (Alternative C risk profile: primarily low risk; high risk during bait broadcast)

Bird	Scientific name	Abundance index				References
		Fall	Winter	Winter residents	Spring	
Spotted towhee	<i>Pipilo maculatus</i>	Fairly common	Absent	Absent	Rare	Richardson et al. 2003
Chipping sparrow	<i>Spizella passerina</i>	Common	Extremely rare	Absent	Fairly common	Richardson et al. 2003
Clay-colored sparrow	<i>Spizella pallida</i>	Fairly common	Absent	Extremely rare	Rare	Richardson et al. 2003
Brewer's sparrow	<i>Spizella breweri</i>	Uncommon	Absent	Absent	Rare	Richardson et al. 2003
Vesper sparrow	<i>Poocetes gramineus</i>	Fairly common	Absent	Absent	Very rare	Richardson et al. 2003
Lark sparrow	<i>Chondestes grammacus</i>	Uncommon	Extremely rare	Absent	Very rare	Richardson et al. 2003
Savannah sparrow	<i>Passerculus sandwichensis</i>	Abundant	Absent	Extremely rare	Uncommon	Richardson et al. 2003
Fox sparrow	<i>Passerella iliaca</i>	Common	Very rare	Rare	Uncommon	Richardson et al. 2003; PRBO unpubl. data
Lincoln's sparrow	<i>Melospiza lincolnii</i>	Common	Absent	Absent	Fairly common	Richardson et al. 2003
White-throated sparrow	<i>Zonotrichia albicollis</i>	Fairly common	Absent	Absent	Very rare	Richardson et al. 2003
White-crowned sparrow	<i>Zonotrichia leucophrys</i>	Abundant	Very rare	Very rare	Common	Richardson et al. 2003; PRBO unpubl. data
Golden-crowned sparrow	<i>Zonotrichia atricapilla</i>	Abundant	Very rare	Uncommon	Fairly common	Richardson et al. 2003; PRBO unpubl. data
Dark-eyed junco	<i>Junco hyemalis</i>	Abundant	Rare	Extremely rare	Common	Richardson et al. 2003

D. Risk profiles for birds

Herbivores (Alternative C risk profile: primarily low risk; high risk during bait broadcast)

Bird	Scientific name	Abundance index				References
		Fall	Winter	Winter residents	Spring	
Lapland longspur	<i>Calcarius lapponicus</i>	Fairly common	Absent	Absent	Extremely rare	Richardson et al. 2003
Lazuli bunting	<i>Passerina amoena</i>	Fairly common	Absent	Absent	Uncommon	Richardson et al. 2003
Bobolink	<i>Dolichonyx oryzivorus</i>	Uncommon	Absent	Absent	Very rare	Richardson et al. 2003
Pine siskin	<i>Carduelis pinus</i>	Common	Rare	Extremely rare	Rare	Richardson et al. 2003

Species in **bold** may be present during bait broadcast. Species not in bold are unlikely to be present during broadcast.

Predators/scavengers* (Alternative C risk profile: primarily low risk; high risk during bait broadcast)

Bird	Scientific name	Abundance index				References
		Fall	Winter	Winter residents	Spring	
American wigeon	<i>Anas americana</i>	Uncommon	Absent	Absent	Absent	Richardson et al. 2003
Mallard	<i>Anas platyrhynchos</i>	Uncommon	Absent	Absent	Extremely rare	Richardson et al. 2003
Northern pintail	<i>Anas acuta</i>	Abundant	Extremely rare	Absent	Extremely rare	Richardson et al. 2003
Green-winged teal	<i>Anas crecca</i>	Fairly common	Extremely rare	Absent	Absent	Richardson et al. 2003

D. Risk profiles for birds

Predators/scavengers* (Alternative C risk profile: primarily low risk; high risk during bait broadcast)

Bird	Scientific name	Abundance index				References
		Fall	Winter	Winter residents	Spring	
Black-bellied plover	<i>Pluvialis squatarola</i>	Common	Very rare	Fairly common	Rare	Richardson et al. 2003; PRBO unpubl. data
Semipalmated plover	<i>Charadrius semipalmatus</i>	Fairly common	Absent	Absent	Absent	Richardson et al. 2003
Killdeer	<i>Charadrius vociferus</i>	Fairly common	Uncommon	Very rare	Very rare	Richardson et al. 2003
Black oystercatcher	<i>Haematopus bachmani</i>	Common	Common	Common	Common	DeSante & Ainley 1980; Ainley & Boekelheide 1990
Spotted sandpiper	<i>Actitis macularia</i>	Uncommon	Absent	Extremely rare	Very rare	Richardson et al. 2003
Wandering tattler	<i>Tringa incana</i>	Common	Very rare	Fairly common	Fairly common	Richardson et al. 2003; PRBO unpubl. data
Willet	<i>Tringa semipalmata</i>	Fairly common	Extremely rare	Fairly common	Very rare	Richardson et al. 2003; PRBO unpubl. data

Codiales (unknown species from the Order)

Cryptoleura ruprechtian

ADMINISTRATIVE REVIEW DRAFT

Appendix I. Brodifacoum toxicity model

For the purpose of estimating individual impacts, representative LD50 values can be used to generalize potential toxicity for birds and mammals ~~respectively~~ (adapted from Erickson and Urban 2004):

- For birds, an LD50 value of 0.26 mg/kg will be used – this is the average LD50 value for the mallard (*Anas platyrhynchos*).
- For mammals, an LD50 value of 0.4 mg/kg will be used – this is the average LD50 value for the laboratory rat (*Rattus norvegicus*)

In comparison to real-world values that toxicologists have obtained from a wide class of species, the values used in this document are conservative; the output of this toxicity model would most likely under-estimate the amount of bait that an individual animal would need to consume to have a 50 percent chance of mortality. This model assumes that an animal's body mass is the primary determinant of how much brodifacoum is required for that animal to reach an LD50 threshold, within each taxonomic category (in this case, birds and mammals). In reality, there are other variables that affect LD50 as well, but using conservative LD50 values such as those above decreases the possibility that the model will under-estimate the risk to individual animals.

Erickson and Urban (2004) use another general model to determine the amount of bait needed to reach an LD50 threshold for birds at a mass of 25 g (e.g. sparrow), 100 g (e.g. turnstone), and 1000 g (e.g. western gull), compared to average daily food intakes for each of these size classes:

Bird size class:	Amt of bait for LD50:	% of daily food intake:
25 g	0.26 g	4.2
100 g	1.04 g	10.8
1000 g	10.4 g	19.2

Erickson and Urban use a similar model to determine the amount of bait needed to reach an LD50 threshold for mammals, using these same size classes. Other than mice, bats are the only mammal taxon on the islands that would fall within the size range of these estimates. All bat species potentially present on the Farallones (see Section 3.4.3.3) are less than 25 g. Erickson and Urban's (2004) model estimates that mammals in this size class would need to consume roughly 10% of their daily food intake as bait pellets to reach an LD50 threshold. This food-intake model is not applicable to pinnipeds, which are orders of magnitude larger than 1000 g.

The following table lists the estimates provided by these models for a number of species present at the South Farallones:

I. Brodifacoum toxicity model

1

Taxon	Est. mass	Appr. amt of bait to reach LD50 of 0.4 mg/kg	% avg. daily food intake#
Greater white-fronted goose	2,075 g (4.57 lb)	21.6 g (0.76 oz)	>20%
California brown pelican*	Small adult: 1.83 kg (4.03 lb)	19 g (0.67 oz)	>20%
Double-crested cormorant*	2,000 g (4.41 lb)	20.8 g (0.73 oz)	>20%
Red-necked phalarope*	32 g (0.07 lb)	0.33 g (0.01 oz)	~4%
California gull**	432 g (0.95 lb)	4.49 g (0.16 oz)**	10-20%
Western gull**	879 g (1.94 lb)	9.14 g (0.32 oz)**	~20%
Glaucous-winged gull**	Similar to WEGU	Similar to WEGU**	~20%
Allen's hummingbird***	3 g (0.007 lb)	0.03 g (0.001 oz)	<4%
Steller sea lion*	Pup: 45 kg (100 lb)	720 g (1.6 lb)	NA
	Adult: 1,088 kg (2,400 lb)	17,400 g (38.4 lb)	NA
Northern elephant seal*	Pup: 34 kg (75 lb)	544 g (1.2 lb)	NA
	Adult: 2,300 kg (5,071 lb)	36,800 g (81.1 lb)	NA

2 * These figures are presented for comparative purposes only, because these species are carnivorous and forage
3 exclusively in the marine ecosystem and brodifacoum ingestion would need to occur either accidentally or through
4 an intermediate prey species (such as fish) that previously consumed bait pellets, an unlikely scenario (Section
5 4.2.3.2).

6 ** Because these birds may be subject to both primary and secondary exposure to brodifacoum, individual birds
7 could reach an LD50 threshold through the consumption of prey animals even if they did not consume this much
8 bait directly.

9 *** These figures are presented for comparative purposes only, because these birds would only be exposed to
10 brodifacoum indirectly through prey animals.

Appendix J. Special Considerations under MMPA

In addition, the Service and its contractors would monitor the response of pinnipeds to all activities, including helicopter operations, bait station installation and maintenance, and other project tasks to ensure compliance with the Marine Mammal Protection Act (MMPA) and the ESA. This observational monitoring is discussed in detail in Appendix J.

ADMINISTRATIVE REVIEW DRAFT

Appendix K. Minimum Requirements Analysis Under the Wilderness Act

See Appendix K for a detailed “Minimum Requirements Analysis” for non-native house mouse eradication on the South Farallones.
